ECOLOGICAL LANDSCAPE ANALYSIS
CUMBERLAND HILLS ECODISTRICT 540

PART 3: Landscape Analysis for
Forest Ecosystem Planners

Ecological Landscape Analysis, Ecodistrict 540: Cumberland Hills

Prepared by the Nova Scotia Department of Natural Resources
Authors: Central Region DNR staff

This report, one of 38 for the province, provides descriptions, maps, analysis, photos and resources of the Cumberland Hills Ecodistrict.

The Ecological Landscape Analyses (ELAs) were analyzed and written from 2005 – 2009. They provide baseline information for this period in a standardized format designed to support future data updates, forecasts and trends. The original documents are presented in three parts: Part 1 – Learning About What Makes this Ecodistrict Distinctive – and Part 2 – How Woodland Owners Can Apply Landscape Concepts to Their Woodland. Part 3 – Landscape Analysis for Forest Planners – will be available as a separate document.

Information sources and statistics (benchmark dates) include:

- Forest Inventory (1995) – stand volume, species composition
- Significant Habitat and Species Database (2007)
- Atlantic Canada Data Conservation Centre (2013)

Conventions

Where major changes have occurred since the original ELA report was written, the new information will be provided in italics, so that the reader can see how some conditions have changed since the benchmark date of the ELA.

Part 3: Landscape Analysis of Cumberland Hills
– For Forest Ecosystem Planners

This in-depth Ecological Landscape Analysis (ELA) report is a lightly edited version of the original ELA produced by Department of Natural Resources (DNR) as an internal document to assist with Crown land planning. The report provides information for planners, forest managers, ecologists, technicians, and woodland owners seeking detailed planning resources. In coming years the DNR will continue to develop landscape planning approaches and introduce additional tools to support sustainable management and biodiversity conservation. The Department is working with stakeholders to explore novel planning approaches using these methods.

The ELA provides tools to recognize and pursue common goals for sustaining ecosystem values across all ownerships within the province’s diverse landscapes. The ELA is not a plan, but instead supports planning by providing a framework of ecosystem mapping, indicators, fine-scaled features, and landscape functions that help describe landscapes as ecological systems. The report comprises the four major sections outlined below, along with theme maps and appendices containing detailed data summaries:

**Understanding the Landscape as an Ecological System**
- Elements Within Landscapes
- Flow-Element Interactions
- Landscape Connectivity

**Landscape Indicators**
- Forest Composition Indicators
- Land Use Indicators

**Fine Scale Features**
- Priority Species and Other Special Occurrences
- Rare Ecossections
- Ecological Representivity

**ELA Summary**
- Element Interpretation
- Ecosystem Issues and Opportunities

**Understanding the Landscape as an Ecological System**
(Appendices 1, 2a, 2b; Map 2)

Landscapes are large areas that function as ecological systems and respond to a variety of influences. Landscapes are composed of smaller ecosystems, known as elements, which were interpreted through analysis using the ecossection layer of the Ecological Land Classification (ELC) for Nova Scotia. Elements are described by their potential vegetation (e.g. climax forest type) and physical features (e.g. soil, landform). These characteristics help determine historical vegetation patterns and promote an understanding of present distributions and potential habitat conditions.
development. Across the province about three dozen elements were identified in the ELAs and mapped to show their distribution across ecodistricts and ecoregions.

**Elements Within Landscapes (Map 2)**

The landscape analysis identified and mapped nine distinctive elements in the Cumberland Hills Ecodistrict – one matrix, seven patches, and a corridor. A matrix is the dominant element. Patches are smaller yet still distinctive elements. Corridors are natural linear elements, such as river valleys, that extend across ecodistricts (see connectivity section for full discussion of matrix, patch and corridor concepts).

Comparisons with current conditions determined that a large portion of the ecological structure has been altered within this ecodistrict. Most of the elements are under moderate to heavy land use pressures.

**Tolerant Mixedwood Hills**, the matrix element representing about half of the ecodistrict, has been altered from what was once a climax forest of shade-tolerant hardwoods – sugar maple, yellow birch, and beech (60%) – and tolerant softwoods – red spruce, hemlock, and white pine (40%) – to a forest with a relatively equal area in all covertypes.

In **Tolerant Mixedwood Hummocks**, much of the largest patch element has been converted to agricultural or other uses. Abandoned farmland has been reforested to white spruce or cultivated to grow wild blueberries. Other patch elements, in order of size, are **Spruce Pine Hummocks**, **Red Spruce Hummocks**, **Wetlands**, **Spruce Hemlock Pine Hummocks and Hills**, **Floodplain**, and **Spruce Pine Flats**.

Numerous valley bottoms and slope systems, represented by **Valley Corridors**, a corridor element, follow the main river valleys and provide linkages to adjacent ecodistricts.

**Flow – Element Interactions (Appendix 1; Map 2)**

Flow phenomena are the features that move across and through landscapes. They can be energy or material, living or non-living. Diaz and Apostol (1992) suggest that the most relevant flows for landscape analysis may include water, wind, fire, animals, plants, and humans. The following flows were considered in the analysis of this ecodistrict and are described in Appendix 1: people, water, deer, moose, furbearers (otters, fishers, beavers), wood turtles, osprey, eagles, and fish.

The main purpose in describing flows, and their relationship to the elements, is to provide insight into the role of each element. This will inform understanding of each element’s contribution to overall landscape function.
**Landscape Connectivity** (Appendices 2a, 2b; Map 2)

Connectivity refers to the ease or difficulty that resources, such as water, animals, or even events—such as fires—can move within an area. As a basic ecological requirement, the ability to move without excessive risk is of critical importance for maintaining biodiversity at all levels, including genetic, individual, species, population, community, and ecosystem.

Connectivity takes many forms and operates at a wide range of scales. Among the structural ecosystem components that support movement, three major systems can be identified:

Matrix Ecosystems – Matrix implies large areas of broadly similar habitat in which movement is not constrained to particular routes. The slow spreading and mixing of species through the dominant community characterizes the ecosystem matrix. This “percolation” is dependent on the large patch conditions, which may be vulnerable to fragmentation. Interior habitat is often an important feature of matrix ecosystems.

Patch Ecosystems – The movement of species among patches of suitable habitat is dictated by the arrangement and size of patches and by a number of species’ specific measures. Patches of suitable habitat must occur at acceptable distances over time. Some patch habitats have critical functions and must be continuously sustained, such as wetlands for migrating birds, feeding areas for deer, and calving grounds for moose. Other patches may be dynamic, shifting about the landscape as ecosystems evolve. Edge and interior habitat conditions are important features of patch ecosystems, as well as natural isolation.

Linear Corridor Ecosystems – Flow along popular routes is dictated by enduring physical features, such as river valleys. Linear flow often requires continuous connection, such as rivers. Breaks in the connection serve as obstacles. It is a characteristic of continuous linear features that they often serve as connective corridors for some species and barriers for others.

As an example of the flow–element interactions, moose and deer move away from the harsh winter climate in the Chignecto Ridges Ecodistrict and into the lower slopes of the Cumberland Hills and Cobequid Hills ecodistricts. Numerous deer wintering areas are found partly or entirely within the Cobequid Hills, usually along the river valleys (Map 2). A high percentage of the forest within the ecodistrict is found in the establishment and young development classes leaving fewer softwood areas for cover and thermal protection. The increased rate of harvest over the past 20 years has altered the ecodistrict to a smaller patch size, where historically, the gap disturbance regime would have much larger patches.

One strategy would be to mimic the gap and infrequent disturbance regime areas by utilizing silviculture treatments such as pre-commercial and commercial thinning that would speed
development of late successional species such as red and black spruce, pine, hemlock, and tolerant hardwoods, creating larger patches and interior conditions.

**Links to Neighbouring Ecodistricts** (Appendices 1, 2a; Map 2)

Four of the landscape flows – people, water, deer, and fish – are identified with major linkages to adjacent areas or ecodistricts (Map 2). The hydrological system provides the most obvious physical connection among the Cumberland Hills, Chignecto Ridges, Northumberland Lowlands, Cobequid Hills, Cumberland Marshes, and Parrsboro Shore ecodistricts. Cumberland Hills is the source of several significant rivers that generally have a south to north flow.

The Black River is the major river in the eastern section of the ecodistrict and drains into the Northumberland Strait. In the western portion of the ecodistrict, many second and third order streams feed into the Maccan River which drains into the Cumberland Basin. Tributaries in the far western tip feed into the Apple River, which drains into the Chignecto Bay.

Other major rivers that provide connection to other ecodistricts are the Fox River, River Hébert, River Philip, Leamington Brook, Wallace River, and the Little Forks River.

Deer move in and out of the Cumberland Hills, shifting south in winter out of the Atkinson Brook, Kelley River, and Apple River toward their wintering areas along the Parrsboro Shore, Halfway River, and Shulie Lake area. Deer also move out of the north-facing lowlands toward wintering areas located at Collingwood Corner and Williamsdale.

People provide linkages among the neighbouring ecodistricts of the Cobequid Hills, Cumberland Marshes, Chignecto Ridges, Parrsboro Shore, and the Northumberland Lowlands through their many activities (recreation, transportation, fishing, forest management, utilities development, and settlements). The major linkages are at Apple River, Harrison Settlement/Newville Lake, Southampton, Leamington Brook, Springhill, Stanley, Collingwood Corner, Wentworth, Greenville, Westchester Station, and Millvale.

Future management activities should recognize significant links to neighbouring ecodistricts and manage these forests in the areas to enhance and sustain connectivity.

**Landscape Indicators** (Appendices 3, 6, 7, 8, 9, 10, 11; Maps 3, 4, 5, 9, 10)

Indicators provide standard measures for assessing landscape conditions. Indicators can be used to develop goals, identify priority actions, assess trends, and support the evaluation of scenarios.

**Forest Composition Indicators** (Appendices 8, 10; Maps 4, 9, 10)

Managing landscapes for biodiversity requires a variety of planning approaches and tools. Sustaining forest composition diversity by reflecting natural patterns of disturbance and succession is one approach that DNR is employing to try and realize this objective. A number
of additional approaches and planning tools are being developed which will be integrated with objectives defined in the ELA protocol.

Human activities, such as forest harvesting, can shape the structure and composition of the forested landscape and should be planned to help support landscape composition goals.

At a landscape planning scale, the variety of habitats can be broadly described in terms of the composition of development classes, seral stages, and covertypes.

**Development class indicators** describe changes in structure and process as forests age and trees grow larger. For landscape management purposes, four development classes are recognized:

- forest establishment (0 to 6 m height)
- young competing forest (7 to 11 m height)
- mature forest (> 11 m height; including multi-aged and old forest)
- multi-aged / old forest (multiple layered / Old Forest Policy)

**Seral stage indicators** describe changes in species composition of forest communities as succession progresses from domination of early seral “pioneer” species following disturbance, toward late seral communities dominated by long-lived, shade-tolerant “climax” species. Seral stage is dependent on the composition of tree species of a forest, irrespective of age. For landscape management purposes, three seral stages are recognized:

- early (seral score 10 to 23)
- mid (seral score 24 to 37)
- late (seral score 38 to 50)

A look-up table (see Appendix 8) assigns each species in the forest inventory a value from one to five representing its position on the successional scale. These values are applied to the species composition data in the forest inventory to calculate a seral score, which may range from 10 to 50.

**Covertype indicators** further refine landscape composition by distinguishing forests of different community conditions. Management generally recognizes three forest covertypes:

- softwood (overstory cover of softwood species is 75% or more)
- hardwood (overstory cover of hardwood species is 75% or more)
- mixedwood (overstory cover of either softwood or hardwood is between 25% and 75%)

**Target Ranges for Composition Indicators**

Table 7 provides target ranges for development class and seral stage composition appropriate for different disturbance regimes. These ranges have been derived from the professional judgment of DNR forest ecologists to guide composition objectives for large landscape areas. This guidance can be used to assess how land holdings contribute to the overall ecodistrict structure by referring to the element analysis section which summarizes the levels of these indicators.

**Forest Vegetation Types for Seral Stages in Each Element**

Each element contains a number of forest stands that can be classified by vegetation, soil, and ecosites. The DNR publication *Forest Ecosystem Classification for Nova Scotia, Part I: Vegetation Types (2010)* (http://novascotia.ca/natr/forestry/veg-types/veg-navigation.asp) is helpful in identifying forest plant communities. Table 8 presents a description of the vegetation types likely to be found within elements, along with the current percentage of each seral stage.

View forest groups and vegetation types at [http://novascotia.ca/natr/forestry/veg-types/veg-navigation.asp](http://novascotia.ca/natr/forestry/veg-types/veg-navigation.asp)

To help with identification of vegetation types, the 14 forest groups in Nova Scotia designated by DNR are: Cedar (CE), Coastal (CO), Flood Plain (FP), Highland (HL), Intolerant Hardwood (IH), Karst (KA), Mixedwood (MW), Old Field (OF), Open Woodland (OW), Spruce Hemlock (SH), Spruce Pine (SP), Tolerant Hardwood (TH), Wet Coniferous (WC), Wet Deciduous (WD)

**Bolded vegetation types** indicate typical late successional community

\(^1\) Forest Ecosystem Classification for Nova Scotia (2010)

*Percentage of element in each successional stage. Percentages may not total 100 due to unclassified lands (such as clearcuts and regenerating stands) not being included.

**Land Use Indicators** (Appendices 3, 4, 5; Maps 6, 7)

Two indices (Ecological Emphasis Index and Road Index) have been developed to measure the relative pressure that current human land use exerts on ecosystems.

**Ecological Emphasis Index** (Appendices 11, 12; Map3)

A variety of land management practices occur across landscapes, ranging from natural reserve areas to highly modified urban environments. Conserving biodiversity requires a balancing of land use practices to sustain ecological integrity.

To assist in assessing land use intensities and develop appropriate practices, four levels of ecological integrity are defined based on the degree that the conservation of natural conditions is emphasized in the management practices and policies applied to the land:

- Reserve, such as parks or wilderness areas
• Extensive, which are lands managed or restored for multiple values using ecosystem-based techniques
• Intensive, optimizing resource production by management techniques that may reduce biological diversity, such as plantations; but also meet the Wildlife Habitat and Watercourses Protection Regulations (NSDNR, 2002) 
  (See http://www.gov.ns.ca/natr/wildlife/habitats/protection)
• Converted, lands altered for agriculture, roads, or other human activities

All lands within the ecodistrict are assessed at the stand level and assigned one of these four ecological emphasis classes (EEC) based on past practices. These classes are mapped over all areas of the landscape using a one hectare grid. The Ecological Emphasis Index (EEI) is determined by assigning a weighting value to each class: Reserve (100), Extensive (75), Intensive (25), and Converted (0). An overall index value may be calculated for any area of interest, such as element, ecosection, ecodistrict, or ecoregion, by averaging the index values within the area to provide a relative indication of land use pressure.

A summary of these land use intensities provides an overall EEI of 57 to 64 for the ecodistrict (Appendices 12a and 12b). This suggests that overall intensity of land use for Cumberland Hills is currently at a moderately changed state that may affect both the structure and function to support habitat (for all species) and for biodiversity conservation.

A GIS-based classification of current land use employing the four ecosystem emphasis classes indicates that 67% of the land inherently capable of supporting forest land falls within the extensive EEC. Lands are managed for multiple values using ecosystem-based techniques that conserve biodiversity and encourage natural ecosystem conditions and processes.

An additional 4% of these lands fall in the intensive EEC and are intensively managed to optimize resource production from sites maintained in a native state (e.g. forested). Despite intensive practices, these lands are an important component of landscape structure and composition. Management may eliminate or reduce the duration of some development processes, particularly mature old forest stages, and may result in non-natural succession, produce unnatural conditions such as plantations containing exotic species, old field white spruce, and monoculture plantations, or reduce structure and composition below ecologically desirable levels.

The remaining lands are split between the reserve class (2%) and the converted class (14%). Fifteen percent of the land falls in the unclassified category.

The reserve class is divided into two categories: legal reserves and policy reserves. Legal reserves are areas that have legal status under the IUCN (International Union for the Conservation of Nature) codes of I, II, or III such as wilderness areas, protected beaches, and designated provincial parks. The second type of reserve is one set aside under various provincial policies, such as for old forests or the Eastern Habitat Joint Venture lands. Representation within Cumberland Hills is relatively low because of the low percentage of Crown land holdings. There is opportunity to add additional lands to the reserve class under the Old Forest Policy by selecting community types that presently have insufficient representation or community types that are rare within the ecodistrict and/or ecoregion.
The converted lands are those areas that have been altered by human settlement, farming, urban development, and transportation and utility corridors. These converted lands are predominately located around the major river corridors, villages, and towns. These lands are given a zero EEI class in their present state but some locations, especially along the river corridors, show opportunity for restorative measures to the predicted climax stands of spruce, elm, sugar maple, and white ash.

DNR will continue to develop and evaluate other measures of conservation risk.

**Road Index** (Appendices 6, 7; Map 5)

The GIS-based “Road Index” provides a standard assessment and mapping of road distributions across ecodistricts to assist planners to objectively explore options for managing road networks and assess the intersection of road affects with other features of the landscape. Density, distance, and type of linear feature (e.g. road types, power lines) are used to calculate index values that indicate relative road pressure. The index value is mapped over all areas of the landscape using a one hectare grid. The overall index may be calculated for any area of interest, such as element, eosection, ecodistrict, or ecoregion, by averaging the index values within the area to provide a relative indication of land use pressure. The index provides a numerical indicator of road influence that can be used to monitor temporal changes and compare different landscapes.

In discussing road ecology, Forman (2004) describes five distinctive landscape types in North America: city-suburb, agricultural, forestry, arid-grassland, and natural landscape. Each landscape type has a characteristic pattern of road networks with distinctive ecological effects and planning considerations (Forman & Hersperger 1996). These were adapted in Nova Scotia to classify five Road Index Benchmark Ranges associated with particular land use settings:

- Remote Landscape (RI 0 to 6): Unpopulated with few roads, trails, or other linear features
- Forest Resource (RI 7 to 15): Forest access roads are the primary linear feature
- Mixed Rural (RI 16 to 24): Mixed land use of rural settlement, forestry, and agriculture
- Agriculture/Suburban (RI 25 to 39): Suburban settlement and/or open agricultural fields
- Urban (RI 40 to 100): Urban environment with high building densities, roads, and few tracts of undeveloped land outside municipal parks

Road, trail, and utility corridors are vital components of human land use. However, transportation systems are expensive and produce many undesirable environmental effects, such as chronic siltation, invasion routes for exotic species, fragmentation, loss of productive land, and increased human presence.

Low road density areas are important features for biodiversity conservation. Planning should consider block scheduling options, life expectancy, class requirements, decommissioning strategies, and overall landscape function, in order to develop efficient access systems designed to minimize environmental impacts.

Cumberland Hills currently has an average RI value of 12 (Appendix 7, Table 3) that falls within the forest resource range of 7 to 15, considered to have mainly forest access roads and trails.
Forty-one percent of the ecodistrict, or 37,055 hectares, falls within this category. Six percent of the ecodistrict has a remote road index value between 0 and 6. These areas of few roads in the remote range are concentrated in the central part of the ecodistrict and are mostly associated with steep dissected ridges, wetland complexes, sensitive areas that surround rivers, or are in close proximity to water supply areas.

As would be expected, the highest road densities occur around the highest settlement areas or transportation systems found in Springhill, Salt Springs, Stanley, Wentworth, and Westchester Valley. Indexes in these areas are in the agriculture and suburban to urban categories (Appendix 7, Table 2 and Map 5). The road index mapping (Map 5) also highlights the area around Halfway River, Southampton, Mapleton, Leamington, and Collingwood Corner and along Highway 204 near West Leicester where high densities of roads bisect the ecodistrict, contributing to habitat fragmentation.

Opportunities for road and trail access in the design phase:

• Improve the distribution and connectivity among the low road density areas (west and east of Springhill, west of Pettigrew Settlement, and South Brook/East Mapleton area) where this may improve the connectivity among natural areas and linkages to the neighbouring ecodistricts of Chignecto Ridges and Cobequid Hills.
• Locate any recreational trails away from wetlands, special management zones, rare and unique wildlife habitat, and utilize old abandoned trails or logging roads before additional trails are constructed.
• Schedule access systems for regular maintenance or decommissioning particularly where connectivity or additional reserves are to be established.
• Include the analysis of road density impacts in all land management planning.
• Conserve the distribution of present areas with low road density.

**Fine Scale Features** (Appendices 3, 4, 5; Maps 6, 7)

Data on the status and location of priority species, ecological land classification, representivity analysis, and other landscape characterization themes were used to identify special occurrences, rare ecosections, and ecological representivity. These fine scale features, which occur at a sub-landscape level, may require special management practices to conserve their uncommon characteristics.

Lindenmayer and Franklin (2002) refer to the importance of identifying “midspatial-scale” features and “patch-level habitats,” including: 1) aquatic ecosystems, such as streams, lakes, and ponds; 2) wildlife corridors; 3) specialized habitats, such as cliffs, caves, thermal habitats, meadows, and vernal pools; 4) biological hotspots or places of intense biological activity, such as calving sites, over wintering grounds, and spawning habitats; and 5) remnants of old forest.

**Priority Species and Other Special Occurrences** (Appendix 3; Map 6)

Landscapes and ecosystems comprise many species of plants, animals, and other organisms. Some of these species are given priority in planning, management, and stewardship because they
are rare, and/or at risk of going extinct locally or on a larger scale. The status and location of these species are important and data are collected, compiled, and assessed on an ongoing basis.

The primary species data used in this report are from the Atlantic Canada Conservation Data Centre and DNR’s Significant Habitat Database. Efforts are made to ensure data are as accurate and up-to-date as possible. Lists and maps indicate what is currently known. Due diligence tied to planning, management, and stewardship may require that surveys be carried out to update information or to fill gaps in our knowledge. Priority species may require special actions in terms of forest management and other activities that alter habitat and the landscape. If more information is required or if management specific to a priority species need to be developed, a regional biologist, Wildlife Division staff, or other species experts should be contacted.

This section includes species at risk (refer to Table 1a, Appendix 3), species of conservation concern (Table 1b, Appendix 3), other conservation features (Table 1c, Appendix 3), and heritage features (Table 1d, Appendix 3, where available). The list of species at risk and species of conservation concern were obtained from the Atlantic Canada Conservation Data Centre (ACCDC) databases, current to 2013.

**Species at Risk**

The term “species at risk” is generally used to describe those species that are, to some extent, protected under provincial or federal endangered species legislation. Usually these species are protected where they occur on provincial, federal, and private lands. In Nova Scotia, the two main pieces of endangered species legislation are the Nova Scotia Endangered Species Act (NSESA) and the federal Species at Risk Act (SARA). Species can be classified as “endangered,” “threatened,” “vulnerable/special concern,” or as “extinct” or “extirpated.” In most cases for species at risk, recovery planning and special management are in place, as well as legal protection (See [http://novascotia.ca/natr/wildlife/biodiversity/at-risk-overview.asp](http://novascotia.ca/natr/wildlife/biodiversity/at-risk-overview.asp)).

**Species of Conservation Concern**

The term “species of conservation concern” refers to those species that are a high priority for conservation and special attention during planning, management, and stewardship. These species may be rare and/or under a variety of threats but the threats do not currently warrant species at risk designation. In some cases these species could meet the criteria for a species at risk but a formal species at risk assessment has not been done. Species of conservation concern are a priority in landscape planning because a focus on them now can prevent these species from becoming species at risk later.

**Species Ranking and Coding Systems**

A number of ranking and coding systems identify and convey the status of species at risk and species of conservation concern. Some of this information is provided in Appendix 3 and Map 6 and is routinely used in planning, management, and stewardship activities.
Colour-coded “traffic light” systems are used provincially and nationally. These systems use “red to orange/yellow to green” categories to indicate the most at risk species (red) to the least at risk species (green). Details of these systems are available from the Wildlife Division.

A second system commonly used is NatureServe Conservation Data Centre system. This system uses numbers from one (extremely) to five (widespread, abundant) to denote the relative rarity and conservation concern for species. At the provincial scale numbers are prefixed with “S” to indicate that this is a state/provincial level rank. Ranks at the National (N) and Global (G) levels are also available for all species. In Nova Scotia, the Atlantic Canada Conservation Data Centre (http://www.accdc.com/) works with partners to provide ranks and data on species’ occurrence.

As of 2013 in the Cumberland Hills Ecodistrict, there are documented occurrences (under the NSESA) of the following number of formally listed species: five endangered, five threatened, and two vulnerable. In addition to the listed species, the National General Status process also identifies seven orange species, 21 yellow species, 20 green species, and two undetermined species for a total of 50 other species of conservation concern in this ecodistrict.

Designated species at risk found within Cumberland Hills include Atlantic salmon, mainland moose, black ash, wood turtle, eastern waterfan lichen, brook floater mussel, and several bird species (common nighthawk, olive-sided flycatcher, eastern wood-pewee, bobolink, barn swallow, bank swallow, and Canada warbler).

Other species of conservation concern known in Cumberland Hills Ecodistrict include yellow-bellied flycatcher and common loon (birds); aloe-like rigid screw moss and toothed-leaved nitrogen moss (bryophytes); red ash, smooth sweet cicely, and northern blueberry (dicots); northern clubmoss and ground-fir (ferns and their allies); mustard white and question mark (insects); cougar (mammals); triangle floater and tidewater mucket (mollusks); Canada lily and hairlike sedge (monocots).

**Birds**

As of 2013, nine species of birds found to be present in the ecodistrict are designated at risk. Eight of these are listed under the NSESA: barn swallow, chimney swift, rusty blackbird, and Canada warbler as endangered; common nighthawk and olive-sided flycatcher as threatened; bobolink and eastern wood-pewee as vulnerable. Nationally, five species are listed under SARA: common nighthawk, olive-sided flycatcher, chimney swift, and Canada warbler as threatened; rusty blackbird as special concern. COSEWIC has designated all nine species: common nighthawk, olive-sided flycatcher, barn swallow, bobolink, bank swallow, chimney swift, and Canada warbler as threatened; blackbird and eastern wood-pewee as special concern.

Generally there has been a nationwide decline in aerial insectivores, which are commonly attributed to a decline in flying insects. Most likely the population decline is influenced by multiple causes such as habitat loss, change across the landscape, and a decline in insects.

The common nighthawk prefers open habitat such as beaches, dunes, grasslands, barrens, pastures, recently cleared lands, and flat graveled roof tops in urban areas. The decline in the
common nighthawk population is likely attributed to habitat loss and modifications along with reduced availability of flying insects.

The olive-sided flycatcher prefers spruce and fir swamps and bogs with open water. This species has experienced long-term declines attributed to habitat loss in wintering grounds, a decline in insects, and climate change.

Eastern wood-pewee can be found in deciduous forests, typically along the edges and in clearings with closed canopy and open understory conditions. This species has declined over the past few decades and almost exclusively feeds on flying insects. The decline in population is most likely attributed to a combination of loss of habitat in the wintering range, current forestry practices, and climate change.

The bobolink is associated with large open grasslands and hayfields. Declines are due to mortality from agricultural practices, habitat loss and fragmentation, and bird control methods.

Barn swallows have declined across North America since the 1980s. These swallows nest at artificial sites, such as barns, under bridges, culverts near farmlands, marshes, lakes, and rural areas. The loss of important artificial nesting substrates and changes to farming practices may be implicated with population declines.

The bank swallow has shown a decline over the past number of years. Bank swallows nest in exposed bank faces that include river banks, hardened sawdust piles, coastal bluffs, and gravel pits. Declines are attributed to loss of nesting, breeding, and foraging habitat.

The Canada warbler has shown significant declines over the past few decades. These warblers can be found in a variety of different habitat types, but prefer mixed forests with dense undergrowth. Population declines are not well understood but habitat loss in the wintering range is most likely a significant influence.

**Plants**

Only one plant species at risk is documented for the Cumberland Hills Ecodistrict: black ash. In 2013, black ash was listed under the NSESA as threatened; there are an estimated 1,000 individuals and only 12 mature trees in the province. There are only three documented locations in the ecodistrict, two on the River Philip and one near Maccan.

**Fish**

There are several significant rivers and their tributaries in the Cumberland Hills Ecodistrict, including River Hébert and the Philip, Black, Little Forks, Maccan, Halfway, Southampton, and Wallace rivers. Historically, Atlantic salmon have utilized many of these rivers for spawning and continue to make some use of the available habitat. The inner Bay of Fundy salmon population has steadily declined over the last 20 years and has been designated as endangered by COSEWIC and protected under the federal SARA. The decline in Atlantic salmon is not well understood but evidence suggests that low marine survival is a primary cause which may be due to ecological
changes in the Bay of Fundy. Other threats to this species include environmental contaminants, habitat loss and degradation, lack of riparian buffers along waterways, water passage obstruction, and lack of pools.

**Insects**

Monarch butterflies are designated by COSEWIC and listed under SARA as special concern but have no provincial listing. Monarchs are grouped with the milkweed butterflies of the family Danaidae, which also includes the viceroy. The monarch is the most common of this group, occurring throughout the United States and southern Canada, and is one of the few butterflies that are migratory.

Monarch habitat in Nova Scotia includes fields, meadows, abandoned farmland, and roadsides that have a presence of milkweed. Monarchs will only lay their eggs on the leaves of milkweed, which is the primary food for the developing caterpillars. The monarch may occasionally be observed in the Cumberland Hills Ecodistrict, along with parts of the province.

**Mammals**

Moose on the mainland of Nova Scotia have been listed as endangered under the NSESA (2003). Mainland moose are genetically distinct from those on Cape Breton Island, where moose populations are healthy. The Cumberland Hills Ecodistrict is an important area for moose as it falls within a large area that has been identified as a significant concentration area for mainland moose. This area is considered to be “occupied moose habitat” (an area with recurrent observations of moose over time) and moose are reported to occur throughout the ecodistrict in low numbers.

Moose are commonly associated with forested landscape habitat that has been altered or disturbed by events such as fire, wind, disease, or timber harvesting. Habitat requirements of moose are largely dependent on successional forest stages. Early successional hardwood trees and shrubs provide important browse while mature conifer cover are valuable for shelter, thermal cover, and protection in winter and summer. Secluded wetland areas with an abundance of emergent vegetation are used for both feeding and cooling during the summer. The availability of suitable habitat for endangered mainland moose is important in maintaining its future presence.

Special management practices for mainland moose are applied for forestry activities on Crown land in designated concentration areas (See [http://novascotia.ca/natr/wildlife/habitats/terrestrial/pdf/SMP_Mainland_Moose.pdf](http://novascotia.ca/natr/wildlife/habitats/terrestrial/pdf/SMP_Mainland_Moose.pdf)).

Application of these practices during forest management planning specifically aims to conserve calving areas, aquatic feeding areas, and thermal refugia. The Forest / Wildlife Guidelines and Standards provide minimal habitat specifications for moose on Crown land through the 8% retention for old growth and maintenance of reasonable age class distribution.
Reptiles

Wood turtles are designated by COSEWIC as threatened and listed under the federal SARA and NSESA. Based on species occurrence information, the Cumberland Hills Ecodistrict is not likely to support a large number of wood turtles. Infrequent sighting reports are associated with River Hébert, Newville Lake, Wallace River, and River Philip. Wood turtles are uncommon province-wide, with the majority of observations occurring at a few main concentration areas. Currently, none of these areas are within this ecodistrict.

Mollusks

Only one mollusk species at risk is documented for Cumberland Hills: the brook floater. In 2013, this freshwater mussel was listed under the NSESA as threatened with only five known locations in the province. The brook floater prefers shallow rivers or streams with a moderate to high water flow. Occasionally they have been found in small lakes with sandy bottoms. Threats to this species include changes to water quality and quantity, often the result of shoreline development, sedimentation, and agricultural practices. One report of this mussel is known for the ecodistrict.

Lichens

The eastern waterfan is designated by COSEWIC as threatened. This lichen prefers shaded streams where it grows at or below water level in cool, clear environments. Environmental changes to these habitats by activities that cause stream siltation, microclimate alterations, changes to water quality, and climate change pose threats to this species. Eastern waterfan is reported at one site near the western boundary of this ecodistrict.

Old Forest

The Interim Old Forest Policy requires a minimum of 8% of Crown land within each ecodistrict be identified and protected. The stands are selected to provide representation of landscape elements with the best old forest and old forest restoration opportunities. In 2012, DNR released an updated Old Forest Policy, containing new integrated resource management (IRM) decision-making procedures. (See http://novascotia.ca/natr/library/forestry/reports/Old-Forest-Policy-2012.pdf).

Rare Ecossections (Appendices 3, 12b; Map 7)

The Ecological Land Classification for Nova Scotia (Neily et al. 2003) classifies ecossections based on similar characteristics of landform, soils, and vegetation. These are the smallest mapped unit, and they repeat within ecodistricts. Ecossections have characteristic natural disturbance regimes and climax types.

Landscape elements were identified by combining ecossections with similar characteristics. Table 9 provides explanations of ecossections and their relationship to elements. Ecossections that are rare (< 2% of ecodistrict area) or under high land use pressure (> 75% land conversion) are identified in Appendix 3.
Seven of the fourteen ecosections (ICSM, IFHO, IFSM, WCDS, WFHO, WFKK, and WTLD) found in the Cumberland Hills Ecodistrict 540 each comprises less than 2% of the ecodistrict (Map 7).

*Ecosection Explanations: For example, in WMHO, W stands for Well-drained under Soil Drainage M stands for Medium-textured under Soil Texture and HO stands for Hummocky under Topographic Pattern

Soil Texture:  C – Coarse-textured soils (e.g. sands)  M – Medium-textured soils (e.g. loams)  F – Fine-textured soils (e.g. clays)

comprise ecossections (WCDS, IFSM, and ICSM) that form less than 2% of the ecodistrict. These same ecossections form less than 2% of the ecoregion.

The WFKK ecossection found within the matrix has a climax community of sugar maple, yellow birch, and beech and forms less than 2% of the ecodistrict and only 4% of the ecoregion. This ecossection is under the highest conversions pressure for any ecossection within the ecoregion, exceeding 50%.

The black spruce community within the IFHO ecossection is also less than 2% of the ecodistrict and under heavy land use pressure. Conversion rates for the black spruce is 44% for the ecodistrict and 22% for the ecoregion. No ecossection is more than 70% converted.

Old growth stands have been identified on 1,200 hectares, or 9.4% of the Crown lands, under the Old Forest Policy.

There is adequate representation, under the policy, for all community types with the exception of the red spruce and eastern hemlock, along with sugar maple, yellow birch, and beech. An additional 60 hectares is required for red spruce and hemlock and 43 hectares for the sugar maple, yellow birch, and beech. The Crown has exceeded the 8% target for all other community types within this ecodistrict.

Opportunities for the design phase and for future management are to implement existing policies and develop additional, effective practices to address fine filter conservation issues such as:

- Uncommon forest species for which genetic viability may be threatened as indicated by DNR’s Endangered Species Rating System – yellow and red listed.
- Fine filter management opportunities related to conservation of significant habits.
- Uncommon community conditions (e.g. old age, large live and dead trees, and species associations). Increase representivity in the uncommon old forest communities as above.
- Implement restorative measures in those community types like yellow birch, sugar maple, and beech stands or the red spruce, hemlock, and white pine where conversion to other species or uses are high.

**Ecological Representivity (Appendices 4, 5)**

Ecological representivity describes the degree that the range of natural ecosystem diversity (elements, ecosections) is secured within reserve systems (e.g. Parks, Wilderness, Old Growth Policy).

The overall goal is biodiversity conservation through protection of natural habitat diversity. Ecological representation is employed as a “coarse scale” ecosystem planning concept. The analysis evaluated and identified the reserve status of the ecossections and climax communities located within the ecodistrict where two levels of reserves were recognized: legally protected reserves, such as Wilderness Areas; and policy protected reserves under the IRM classification to include old forest, Eastern Habitat Joint Venture Sites, non-designated provincial park reserves, and non-designated sites of ecological significance.
Designated provincial parks and park reserves, wilderness areas, operational non-designated parks and park reserves, and sites of ecological significance under moratorium are the legal reserves under the IUCN I, II, III, accounting for 90 hectares, or 0.1%, of this ecodistrict (Appendix 4).

An additional 1,219 hectares are defined as policy reserves, including old forest sites set aside under the provincial Old Forest Policy along with designated provincial parks and park reserves, operational non-designated parks and park reserves, and wildlife habitat sites under Eastern Habitat Joint Ventures. These two reserve classes – legal and policy – account for 1,309 hectares, or 1.4%, of the area of Cumberland Hills.

Since provincial Crown lands only represent about 14% of the ecodistrict, opportunities to improve representation may have to be directed to private lands in the form of Eastern Habitat Joint Venture programs, Nature Conservancy of Canada, Nova Scotia Nature Trust, and other groups. Priority sites and strategies to improve representation in the design phase should include:

- Uncommon or rare climax community types, such as black spruce (< 2% in the IFHO ecosection in the ecodistrict and less than 2% in the ecoregion), red spruce, hemlock, and white pine (< 1% in the WCDS ecosection within the ecodistrict and ecoregion) and those under heavy land use pressures, such as sugar maple, yellow birch, and beech (in the WFKK ecosection forming less than 2% in the ecodistrict and less than 5% in the ecoregion) and under conversions that exceed 50% in the ecodistrict and 25% in the ecoregion.
- Additional old forest in the red spruce and hemlock community.
- Improved connectivity between and among the wetland complexes and the river corridors.

**ELA Summary**

**Element Interpretation** (All appendices and maps)

The Cumberland Hills Ecodistrict is defined by rounded hills that seldom exceed 150 metres above sea level. Exceptions occur near Springhill and Leicester where elevations are just over 180 metres.

The bedrock geology is generally Carboniferous era sedimentary rocks such as sandstone, shale, conglomerate, and coal. Leicester Ridge divides two watersheds, with the Little River draining east to the River Philip, and the Little Forks River flowing west to the Maccan River. Near Springhill, the Black River flows to the Maccan River.

The majority of soils in this ecodistrict are derived from sandstones and conglomerates creating well-drained, coarse-textured, sandy loams. A few areas of finer-textured soils such as clay loams have developed from shales and mudstone, and are usually imperfectly drained. The upland sites are a mixture of tolerant softwood and hardwood stands, including red spruce, sugar maple, beech, and yellow birch. Imperfectly drained sites are occupied by black spruce.
Areas with coarse-textured soils are prone to moisture deficits in the summer and are susceptible to fire. Examples of jack pine, white pine, and black spruce on fire-disturbed sites are scattered near Springhill and along the Little Forks River.

Along with fire, natural disturbances on the better-drained sites with tolerant species include blowdown and insect mortality.

**Tolerant Mixedwood Hills**  
(Matrix) (WCKK, WMKK and WFKK ecosctions) (45,500ha)

This matrix element is approximately 45,500 hectares and extends throughout the entire ecdistrict. This element is almost evenly split between the three covertypes: softwood, mixedwood, and hardwood.

Late successional red and black spruce dominate the softwood stands.

Mixedwood stands now comprise some 33% of the area with mid-seral species of red spruce, balsam fir and red maple dominating.

The once dominating hardwood covertype has been reduced to 28% of the element with early and mid-successional species of grey birch, white birch, and red maple dominating.

**Flows**

People (roads, timber, recreation, hunting, fishing, trapping, sugar maple.); water (catchment, filter, groundwater recharge); deer (browse, shelter general percolation); moose (browse, shelter); furbearers (travel, hunting).

**Desired Condition**

The desired condition is a mixedwood covertype of late seral softwoods; red spruce, hemlock, and white pine on the flats and lower elevations along with hardwood stands of sugar maple and yellow birch on the well-drained upper slopes.
Issues

- A high percentage of forested lands within these limits that has been converted to other uses as reflected in the lower EEC Index range (Appendix 12b). The higher land use pressures and conversions are associated with these ecoregions: WCKK, WMKK, and WFKK.
- A high percentage of the forest area within the establishment development class and early and mid-seral successional stages.
- Element is characterized by a structure that has resulted in fragmentation.
- Overall, 8% of the Crown lands have been set aside under the Old Forest Policy within this ecodistrict. There is a slight gap of 75 to 100 hectares required within the sugar maple, yellow birch, and beech community type.

Tolerant Mixedwood Hummocks
(Patch) (WCHO ecoregion) (17,180 ha)

This element type historically contained a mixture of softwood and hardwood stands located on well-drained rocky, fertile, sandy loams of the Rodney and Westbrook soil series. It is a series of small, medium, and fairly large areas distributed over the entire ecodistrict.

This patch still contains softwood and hardwood cover types but 32% (Appendix 10) of the forested area is now mixedwood stands of red maple, white birch, red spruce, balsam fir, aspen, and scattered sugar maple and yellow birch. There is a slight overabundance of forest in the establishment class located predominately in the unclassified lands, late seral softwoods, mid-seral mixedwoods, and early seral hardwood stands. There is only 32% of the forest in late successional species dominated by red and black spruce, scattered pine, hemlock, sugar maple, and yellow birch. Fifty percent of the forest is in the early and mid-successional stages with aspen, red maple, balsam fir, white birch, white spruce, and red spruce dominating.

Flows

People (forestry, roads, hunting, trapping, settlement and recreation); water (catchment, filter); deer (wintering area); moose (local population); furbearers (habitat - fisher).

Ecological Landscape Analysis of Cumberland Hills Ecodistrict 540
**Desired Condition**

A mixed covertype patch with late seral species of red spruce, hemlock, pine, sugar maple, yellow birch, and beech with at least 60% of the forest communities in the mature development class.

**Issues**

- Relatively small stand or area size within this element type.
- High percentage of early and mid-successional species of aspen, red maple, white birch, and balsam fir in the mixedwood and hardwood stands.
- Sixteen percent of the WCHO has been converted to other uses. Restorative measures are needed around Halfway River, River Hebert, Rodney, River Philip, and Millvale.
- Improving connectivity to larger areas that have low road densities, such as the Rodney and Polly Brook areas.
- Create browse for moose and deer.
- Manage on medium to long rotation (presently 50% of the forest within this element is made up of early and mid-successional species).
- There is no representation within the WCHO ecosection under legal reserves. Fifteen percent of the area under Crown lands has been set aside under policy reserves.

**Spruce Pine Hummocks**

(Patch) (ICHO, IMHO and IFHO ecosections) (14,472 ha)

This element type comprises several areas in a variety of sizes. The larger areas are most prominent at Springhill, South Brook, and Little Forks. There is a good distribution of the forest in all development classes and seral stages. The mid-successional species of red and black spruce, balsam fir, and red maple dominate the mixedwood stands.

Aspen, red maple, white birch, and balsam fir dominate the hardwood stands. Mature black spruce dominates the softwood covertypes. Conversion to other land uses for the dominant ecosections (ICHO) is less than 5%. The EEI range is 60 to 68.

**Flows**

People (forestry, roads, hunting, trapping, agriculture, fish ponds); water (filter, catchment basins, groundwater recharge, headwaters); deer (habitat, deer wintering areas); furbearers (habitat, otter, bobcats, fisher).

Desired Condition

Late seral softwood stands of black spruce in a variety of patch sizes and seral stages. Inclusions of both intolerant and tolerant hardwoods on the better-drained knolls. Improved connectivity (for wildlife) between softwood patches, wetlands, and corridors.

Issues

- Fragmentation issues around Little River/Little Forks and Springhill area.
- Unbalanced successional stages in the mixedwood and hardwood stands with early and mid-seral species dominating.
- 44% conversion to non-forest uses within the IFHO ecosection.
- Only 2.6% of element type has policy representation. Twelve percent of the Crown lands have policy reserves under the Old Growth Policy with no legal representation on Crown or private lands for these ecosections within this element type.

Red Spruce Hummocks
(Patch) (WMHO and WFHO ecosections) (5,102 ha)

A fairly prominent well-drained element type that is somewhat fragmented and now found in three general locations: Athol Road, Little River and West New Annan. The element is inherently a red spruce community that has shifted to fairly balanced covertypes of softwood, mixedwood, and hardwood.

Intolerant hardwoods stands of aspen, red maple, white birch, balsam fir, and spruce now dominate the patch type. Softwood stands of mature late seral red and black spruce, white pine with minor amounts of balsam fir and white spruce comprise some 30% of the element. The development classes are fairly well-balanced for the disturbance regime.

The ecological emphasis class is fairly high at 63 to 70 (Appendix 12b). The ecosections (WMHO, WFHO) have relatively low conversions. These same two ecosections are under much higher land use pressure within the ecoregion, where conversions to other uses are 34% and 27%.

Ecological Landscape Analysis of Cumberland Hills Ecodistrict 540
**Flows**

People (settlement, farming, hunting, fishing, trapping, recreation); water (filter, catchment, groundwater recharge); deer (general habitat); furbearers (habitat, fisher, mink, otter); osprey (hunting, nesting); eagles (hunting, nesting).

**Desired Condition**

Late successional softwood stands and softwood-dominated mixedwoods with a variety of area sizes and development classes applicable to the natural disturbance regime (NDR).

**Issues**

- A high percentage of mid-successional species in the mature mixedwood stands and also early successional species in the hardwood stands (Appendix 10).
- Relatively high conversion rates for this community type within these ecossections in other ecodistricts of this ecoregion (Appendix 3, Table 2).
- Relatively small stands size/fragmentation around Little River and Thompson Reid Meadow.
- Maintaining a balance of the forests within each of the development classes.
- Small percentage of Crown land (9%) (Appendix 4) within this element type.
- Element represents only 5.6% (Appendix 12b) of the area of the ecodistrict.
- Uneven distribution of ecossections by ownership.

**Wetlands**

(Patch) (WTLD ecossection) (1,046 ha)

Two fairly large but isolated wetland complexes are located at Thompson Reid Meadow and the Stanley Road, north of Highway 104 in the Black River Area. These wetland patches are characterized by imperfect to poorly drained soils, stunted black/red spruce, white pine, balsam fir, and poor-quality intolerant hardwoods.
These wetlands have an extremely high importance as catchment basins, filters, and groundwater recharge areas, habitats for muskrats and beavers. Old forest representation is present around these complexes.

**Flows**

People (recreation, fishing, trapping, duck hunting); water (filter, catchment, groundwater recharge); deer (food, habitat); moose (limited seasonal use); furbearers (habitat-muskrats and beaver); osprey (nesting, feeding); fish (trout).

**Desired Condition**

Wetlands and wetland complexes all connected and interconnected to hydrological system.

**Issues**

- Loss of wetlands and destruction of these ecosystems.
- Low connectivity which may lead to a barrier or impediment to functionality.
- Education and public awareness of the importance of wetlands.

**Spruce Hemlock Pine Hummocks and Hills**

(Patch) (WCDS ecosection) (896 ha)

This patch element is fairly small and localized to the Mapleton and Leamington Brook areas. The element is inherently a well-drained coarse-textured series of dissections running in a north-south direction with spruce, pine, and hemlock dominating. Thirty-seven percent of the area is now dominated by mature, late seral hardwood stands of yellow birch and sugar maple. Mixedwood stands for red and black spruce, aspen, balsam fir, red maple, sugar maple, and yellow birch represent 28% of this element type.

The development classes are fairly well-balanced for the infrequent disturbance regime. The ecosection type in this element represents less than 2% of the ecodistrict and ecoregion. Conversion is 4% (Appendix 3, Table 2) within the ecodistrict and ecoregion.
Flows

People (hunting, fishing, trapping, forestry); water (major drainage - steep slopes to small interval areas); deer (travel); furbearers (habitat-fisher, otter); osprey (hunting); eagles (hunting).

Composition

Cumberland Hills Ecodistrict 540 (based on statistics up to 2006)

Desired Condition

A mixture of late seral dominated softwood stands of spruce, hemlock, and pine with tolerant hardwood-dominated mixedwoods of sugar maple, yellow birch, hemlock, spruce, and pine. The element would also contain tolerant hardwood stands of yellow birch and sugar maple on the better-drained slopes and hilltops.

Issues

- 17% of the rare ecossection in this element is unclassified.
- Element has low percentage of softwood covertype (31%).
- Mixedwood covertype has high percentage of forests in the mid-successional stage.
- Small patch type has local presence only which may be an impediment to functionality.
- Only 3% of this element type has representation. There are no old forest selections or policy reserves for this rare ecossection type.

Floodplain

(Patch) (IMSM ecossection) (682 ha)

Long narrow wetland complexes parallel to the main corridors located at Halfway River, River Hébert, West Brook, Southampton River, Leamington Brook, and the Wallace River. These wetlands are smooth, low imperfectly to poorly drained areas that are partially treed with stunted spruce, larch, fir, scattered pine, and poor-quality intolerant hardwoods.

On the outer edges of these wetlands, where the soils are well-drained to imperfectly drained, there are scattered elm, sugar maple, and ash.
**Flows**

People (recreation, fishing, trapping, duck hunting); water (filter, catchment, groundwater recharge); deer (food, habitat); moose (limited seasonal use); furbearers (habitat-muskrats and beaver); osprey (nesting, feeding); fish (trout).

</tbody>
</table>

**Desired Condition**

Undisturbed wetlands and wetland complexes connected to and parallel to the river corridors.

**Issues**

- High conversion rates within both the ecodistrict (21% conversion) and the ecoregion (29%).
- Small element size (682 ha).
- Only 4% of this element type has representation with the majority of that area under policy reserves.

**Spruce Pine Flats**

(Patch) (IFSM and ICSM eosections) (605 ha)

This is a small, isolated softwood element of 605 hectares, located in West Leicester. This patch element type is predominately red and black spruce, scattered balsam fir, eastern hemlock with small mixedwood and hardwood stands dominated by red maple, aspen, and white birch. Scattered yellow birch can be found on the deeper well-drained soils. The development classes are fairly well-balanced for the disturbance regime. Fifty-three percent of the forest within this element is in the late seral stage. This element type has a fairly high EEC of 61 to 68.

**Flows**

People (agriculture, recreation-snowmobiling, cross country skiing, hiking, fishing, trapping, local transportation); water (filter, catchment basins); deer (habitat); furbearer (mink, fisher, and otter); osprey (nesting, hunting); eagles (hunting, nesting).
Composition

<tr>
<td></td>
</tr>
</tbody>
</table>

**Desired Condition**

Spruce-dominated softwood stands with a mixture of hemlock and white pine along with mixedwood stands of spruce, pine, hemlock, red maple, and white birch in a variety of development classes and seral stages.

**Issues**

- Approximately 23% of the red spruce, hemlock, and pine has been converted to non-forest uses.
- A high percentage of mid-successional species in this element type.
- High land use pressures especially in the red spruce, hemlock, and white pine communities.
- Small element size.
- Under-representation in the two climax communities of black spruce and also red spruce, eastern hemlock, and white pine. No representation of these two ecosections – IFSM and ICSM – within Cumberland Hills.

**Valley Corridors**

(Various ecosections) (4,654ha)

Valley Corridors is for the most part river corridors that dissect the ecodistrict in several locations. The Cobequid Hills Ecodistrict contains the headwaters of several rivers. The headwater streams are important rivers in the eastern section of the ecodistrict, which drains north into the Northumberland Strait.

In the western section, many of the second and third order streams feed into the Maccan River which drains into the Cumberland Basin. The tributaries at the western tip of the ecodistrict feed into the Apple River, which drains into Chignecto Bay.

This element is generally late successional black spruce, red spruce, hemlock, and white pine with the higher slopes and knolls being gap-disturbed with elm, sugar maple, yellow birch, and ash. Red and black spruce dominate the softwood communities along with scattered balsam fir,
white spruce, and white pine. Mature mid-successional species such as red maple, balsam fir, and red spruce dominate the mixedwood stands that comprise 25% of the corridor communities.

Mature early successional species of aspen, white birch, and balsam fir dominate the hardwood stands. Only 2% of the forest within the corridors is long-lived late successional hardwoods of sugar maple, yellow birch, elm, and ash.

**Flows**

People (trapping, hunting, fishing, forestry, transportation, agriculture, hiking, recreation, water supply - Leamington Brook, settlement, mining - North East Branch Maccan River); Water (filter, catchment, drainage, headwaters - Little Forks River (Chase Lake); deer (seasonal travel, water, habitat, deer wintering areas - Millvale, River Hébert (Newville Lake), Fox River); Moose (seasonal travel - Fox River, River Hébert, River Philip, Millvale, Leamington Brook, Little Forks River); furbearers (basic habitat, movement, food); osprey (hunting, nesting - River Hébert, River Philip, Wallace River, West Branch Wallace River, East Branch Maccan, North East Branch Maccan River); eagles (hunting and nesting - Fox River, River Hébert, River Philip, Wallace River, West Branch Wallace River, North East Branch Maccan River).

</tbody>
</table>

**Desired Condition**

A series of well-connected slopes and intervales in a natural forest condition.

**Issues**

- Non continuous forest cover as a result of settlement, agriculture, and forestry.
- Slightly unbalanced development class. Fifty-one percent of the forest is in an early and mid-seral stage.
- Quantity of representation within the element type is a gap.
Ecosystem Issues and Opportunities (All appendices and maps)

Management of the forest resource in the Cumberland Hills Ecodistrict should focus on forest biodiversity conservation across the range of spatial scales. General principles could include maintenance of connectivity, maintenance of landscape heterogeneity, maintenance of stand structural complexity, and maintenance of the integrity of aquatic systems (Lindenmayer and Franklin 2002). Actions taken toward these principles could consider:

- Gaps within the Cumberland Hills Ecodistrict are usually directly related to an under representation in both the forest community types (sugar maple, yellow birch as beech as well as the red spruce, hemlock) and rare or uncommon ecosystems.
- High percentage of forested lands converted to other uses (associated with WFKK, ICSM, IFHO, IMSM, WMKK, and WCHO ecosections).
- Preservation of wetlands and wetland complexes with their unique, rare, uncommon, or threatened species.
- Fragmentation around Little River and Thompson Reid Meadow.
- The high percentage of early and mid-seral species in most element types.

Cumberland Hills is now a somewhat changed structure that does not represent the inherent natural conditions that once characterized this landscape. Human land use, transportation systems, and utility corridors have fragmented some of the element types, reducing the connective function of the corridors for some species and may also increase the barrier effect of the corridors for species that must move across (Map 5).

An additional concern inherent in ecological planning is the maintenance of connectivity among conservation areas (including wilderness, old growth, provincial parks, and ecological reserves), which are often not ecologically related. At the landscape scale of planning, connectivity among these areas is supported by the dominant forest structure. Connectivity will be sustained by applying the NDR guidelines for landscape composition and recognizing natural linkage opportunities.

Recommendations for connective management strategies include:

- Mitigating the potentially negative barrier effects of concentrated land use in the valley corridors by sustaining and restoring natural communities in key areas such as those identified during the landscape analysis.
- Enhance connectivity between conservation areas by applying appropriate medium and high biodiversity emphasis standards when managing areas with natural linkage potential.
- Improve ecoregional connectivity by sustaining and restoring natural conditions at important linkage points among ecodistricts, as identified in the section Links to Neighbouring Ecodistricts section.

Future management opportunities include implementing existing policies and developing additional, effective practices to address fine filter conservation issues such as:
• Conservation of uncommon forest species for which genetic viability may be threatened as indicated by endangered species’ rating systems.
• Conservation of significant habitss.
• Uncommon community conditions (e.g. old age, large live and dead trees and species associations) and increased representivity in the uncommon old forest communities.
• Implementation of restorative measures in community types such as yellow birch, sugar maple, and beech stands or the red spruce, hemlock, and white pine stand where conversion to other species or uses is high.

### Appendix 2b: Connective Management Strategies

<table>
<thead>
<tr>
<th>Structure Type</th>
<th>Attributes</th>
<th>Conditions of Concern</th>
<th>Management Strategies</th>
</tr>
</thead>
</table>
| **Matrix**     | percolation, large patch, interior habitat | fragmentation, excessive edge | 1. Promote contiguous forest structure using strategies such as patch aggregation and overstory sustaining selection cutting  
2. Promote large patch structure and interior conditions  
3. Mitigate large scale, long term, fragmentation of the matrix that could impede percolation  
4. Manage age and structure appropriate to NDR. For gap and infrequently disturbed ecosections maintain 60% mature cover |
| **Patch Ecosystems** | patch size, nearest neighbour, edge / interior, intervening habitat condition | undesirable connections, internal composition, excessive separations, threats to key patch | 1. Identify and map key patch representatives (high quality, or critical link/distance)  
2. Maintain natural isolations, as well as necessary “nearest neighbour” distances  
3. Identify potential metapopulation habitat dynamics (if applicable) |
| **Linear Corridors** | continuous connection | barriers, interruptions, excessive edge | 1. Mitigate unnatural barriers  
2. Map and Manage along natural boundaries  
3. Conserve “interior” conditions where appropriate through strategic management of neighbouring ecosystems  
4. Sustain continuity, through management of overstory and interior structure appropriate to NDR  
5. Follow habitat regulations for buffer management. Establish wider buffers with natural boundaries along major waterways |

### Table 2: Comparison of Ecological Emphasis Classification Index by Ecosection (Within Ecodistrict and Ecoregion)

Ecosections that form 2% or less of the ecodistrict and/or ecoregion area or are more than 75% converted are highlighted. The table provides a sense of how unique or uncommon an ecosection and its associated climax communities are within the ecodistrict and across the ecoregion. The EEC Index value conveys an indication of relative land use pressure on the ecosection.

Some of these programs may occur in the same area. For example, much of the Old Forest Policy forests are located in the Wilderness Areas.
Appendix 6: Description of Road Density Index

Road, trail, and utility corridors provide the background structure for transporting people and goods and are integral components of human land use. However, transportation systems are expensive and have a wide range of negative environmental impacts including, watercourse siltation, habitat fragmentation, dispersal obstruction, plant and animal mortality, exotic species invasion, loss of productive land, and an overall increase in human presence (Forman & Deblinger 2000, Reed et. al. 1996, Lindenmayer & Franklin 2002).

Efficient access systems can be strategically designed to minimize environmental impacts by incorporating factors such as harvest scheduling, life expectancy, location, road class requirements, decommissioning, and mitigation measures (Lindenmayer & Franklin 2002, Forman, 2004). Selection of transportation routes should incorporate knowledge of landscape functions to improve compatibility with natural ecosystem flows and connectivity (Forman & Hersperger, 1996). Furthermore, areas without roads and/or few roads are important for biodiversity conservation and should be considered during planning (USDA Forest Service 1999).

The GIS-based “Road Index” procedure calculates and maps the spatial influence of the transportation network. It is a management tool designed to help planners gauge the relative influence of man-made linear features within landscapes. It was designed to help integrate the transportation system into an ecological landscape analysis process. In addition to mapping, the index provides a numerical indicator of road influence that can be used to monitor temporal changes and compare different landscapes.

Main Concepts

The influence of the transportation network on the ecological landscape varies with three main factors: 1) the type of transportation feature (e.g. highway, power line, trail, etc.); 2) the density of linear features in a given area; and 3) the distance of an area from transportation features (Forman 2004, Lindenmayer & Franklin 2002, Forman & Deblinger 2000). The Road Index is a weighting of these three factors reflecting their relative influence on ecosystem function.

Road density has a well-documented influence on many factors, including wildlife movements, fragmentation, human access, hydrology, and fire patterns (Forman and Hersperger, 1996). Forman & Deblinger (2000) report great variance in road effect zones, with average cumulative effects extending 300 metres from road edges, and some impacts penetrating up to a kilometre. Consequently, Index values are determined by assessing the transportation network within a one kilometre radius. The Index algorithm is applied to a grid of one hectare squares.
representing the landscape in question. The calculation provides a measure of the density of the transportation network and the specific distance to the transportation features. The resulting index values are scaled to provide a potential range of 0 to 100. For the purpose of map interpretation these values have been grouped into benchmark ranges that reflect characteristic patterns of land use in Nova Scotia.

In Nova Scotia, as in most populated jurisdictions, transportation networks are continuously changing as new roads and utilities are constructed and unused roads and trails deteriorate. As such, any analysis of the current state of these features must be based on reasonably up-to-date data. In this province, the Geomatics Centre, administered by Service Nova Scotia and Municipal Relations, is responsible for mapping transportation features which they include in their 1:10000 topographic series mapping.

On a provincial level, this work is updated on a ten-year repeat cycle and includes changes to existing features and the delineation of new features. Before undertaking road analysis, the Geomatics Centre should be contacted to ensure that the most current data is used to calculate the Road Index values. This data should be further updated using Landsat satellite imagery to add significant new roads and utilities that are over 500 metres in length on lands currently with a remote or forest resource index value.

DNR Forestry Branch maintains a table relating the topographic series attribute coding used by the Geomatics Centre to the feature categories used in the Road Index calculations, along with ArcView programs allowing the data to be formatted correctly. An inventory of recent Landsat satellite images is also available.

Full report contained in the Ecological Landscape Analysis Guidebook
### Appendix 7: Road Density Index Worksheets

Road index values for all tables are benchmarks that will be monitored over time to evaluate trends.

A look-up table assigns each species in the forest inventory a value from one to five for its position on the successional scale. The look-up table may change by ecodistrict since climax on the coast or the Cape Breton Highlands differs from inland and lowland districts. This successional value is multiplied by the species’ percent in the stand to give a stand successional score. Each stand may have up to four species, and the four percentages add to 10, so the stand successional scores range from 10 to 50. These scores are subdivided into three successional categories: 10 to 23 early, 24 to 37 mid, and 38 to 50 late.

Source: Crown Lands Forest Model Landbase Classification.
## Appendix 11: Ecological Emphasis Classes and Index Values

The classification includes all upland conditions, both forested and non-forested, under all types of administration and land use practices. It does not include water or other non-terrestrial conditions.

<table>
<thead>
<tr>
<th>Ecological Emphasis Class</th>
<th>Conservation Factor</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reserve</td>
<td>1</td>
<td>• Reserved lands which meet biodiversity conservation goals through preservation of natural conditions and processes. Resource management activities are not usually permitted except where required to perpetuate desired natural conditions. This class is assigned based on the types of laws and policies governing the management (for example: Wilderness, Parks, Conservation Easement, Old Forest Policy).</td>
</tr>
</tbody>
</table>
| Extensive                 | 0.75                | • Lands managed for multiple values using ecosystem-based techniques that conserve biodiversity and natural ecosystem conditions and processes.  
• Forestry practices employ ecosystem-based prescriptions which consider natural disturbance regimes, successional trends, structure, and composition. Natural regeneration is favoured to provide the next forest. Practices may include protection from fire and insects.  
• Management complies with the Forest Code of Practice and excludes the use of herbicides, exotic tree species, off-site native species, genetically modified organisms, and stand conversion. |
| Intensive                 | 0.25                | • Lands managed intensively to optimize resource production from sites maintained in a native state (e.g. forested). Despite intensive practices, these lands are an important component of landscape structure and composition.  
• Management may eliminate or reduce the duration of some development processes, particularly mature old forest stages, and may result in non-natural succession. Practices may produce unnatural conditions such as exotic species, old field spruce, and monoculture plantations, or reduce structure and composition below ecologically desirable levels. Forests are protected from fire, insects, and competing vegetation.  
• Management adheres to environmental regulations and policies such as the Wildlife Habitat and Watercourse Protection Regulations and Forest Code of Practice. |
| Converted                 | 0                   | • Land converted to an unnatural state for human use, or areas where practices have significantly degraded site productivity (e.g. agriculture, urban development roads, Christmas trees, seed orchards, forest soil compaction). |

These classes have been given a weighting percentage representing their ecological emphasis level: Reserve (100), Extensive (75), Intensive (25), and Converted (0). These percentages are applied to the area of land in each class to determine the “effective area” which is divided by “total area” to calculate the index.

The Unclassified land is too young to determine if it is being managed extensively or intensively. Therefore, an EEI range is reported based on it being all one or the other.

Water was not included as an element type. Areas were rounded to the nearest hectare.

EEI values are benchmarks that will be monitored over time.

### Appendix 13:

#### Glossary B: Terms in Parts 1, 2, and 3

<table>
<thead>
<tr>
<th>Term</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Aspect</td>
<td>The direction of a downhill slope expressed in degrees or as a compass point.</td>
</tr>
<tr>
<td>Atlantic Coastal Plain Flora (ACPF)</td>
<td>A group of 90 species of taxonomically unrelated wetland plants that inhabit lake and river shores, bogs, fens, and estuaries and which are found primarily in southwestern Nova Scotia. The distribution of this group of plants extends down the eastern coast of the USA with isolated populations in Nova Scotia and along the Great Lakes.</td>
</tr>
<tr>
<td>Biodiversity</td>
<td>The diversity of plants, animals, and other living organisms, in all their forms and level of organization, including genes, species, ecosystems, and the evolutionary and functional process that link them.</td>
</tr>
<tr>
<td>Canopy</td>
<td>The uppermost continuous layer of branches and foliage in a stand of trees.</td>
</tr>
<tr>
<td>Climax forest community</td>
<td>A relatively stable and self-perpetuating forest community condition that maintains itself (more or less) until stand-level disturbance causes a return to an earlier successional stage. The final stage of natural succession for its environment.</td>
</tr>
<tr>
<td>Climax vegetation</td>
<td>A forest or non-forest community that represents the final stage of natural succession for its environment.</td>
</tr>
<tr>
<td>Coarse filter approach</td>
<td>A habitat-based approach to conserving biodiversity by maintaining a natural diversity of structures within stands, and representation of ecosystems across landscapes. The intent is to meet the habitat requirements of most native species over time. Usually combined with a fine filter approach to conserve specific rare species and ecosystems.</td>
</tr>
<tr>
<td>Coarse Woody Debris (CWD)</td>
<td>Dead tree stems greater than 7.5 centimetres in diameter and laying horizontally at 45 degrees or less. Provides habitat for many species and is a source of nutrients for soil development.</td>
</tr>
<tr>
<td>Commercial thinning</td>
<td>Silviculture treatment that “thins” out an overstocked stand by removing trees that are large enough to be sold as products, such as poles or fence posts. This treatment is carried out to improve the health and growth rate of the remaining crop trees.</td>
</tr>
</tbody>
</table>
**Composition**
The proportion of biological components within a specified unit such as a stand or landscape:
- **Stand or Species Composition.** The proportion of each plant species in a community or stand. May be expressed as a percentage of the total number, basal area, or volume of all species in that community.
- **Landscape Composition.** The proportion of each community type within a landscape. Community type may be defined by vegetation type, covertype, seral stage, or development class (age).

**Connectivity**
The way a landscape enables or impedes movement of resources, such as water and animals.

**Converted**
Lands removed from a natural state (e.g. forest) and changed to other uses (e.g. agriculture, urban, settlement, road).

**Corridor**
Corridors are natural linear communities or elements, such as river valleys, that link parts of the ecodistrict. They are a fundamental feature of the “matrix, patch, corridor” concept of landscape structure.

**Crown land and Provincial Crown land**
Used in the Ecological Landscape Analysis to include all land under the administration and control of the Minister of Natural Resources under the Forests Act, Section 3; as well as the lands under the administration and control of the Minister of Environment under the Wilderness Areas Protection Act. Also includes Federal Parks in the accounting of protected area representation.

**Covertype**
Refers to the relative percentage of softwood versus hardwood species in the overstory of a stand. In this guide, covertype classes are:
- **Softwood:** softwood species compose 75% or more of overstory
- **Hardwood:** hardwood species compose 75% or more of overstory
- **Mixedwood:** softwood species composition is between 25% and 75%

**Development class**
The description of the structure of forests as they age and grow (e.g. establishment forest, young forest, mature forest, multi-aged / old forest).

**Disturbance**
An event, either natural or human-induced, that causes a change in the existing condition of an ecological system.

**Ecodistrict**
The third of five levels in the Ecological Land Classification for Nova Scotia Volume 1, and a subdivision of ecoregions. Characterized by distinctive assemblages of relief, geology, landform, and vegetation. Used to define the landscape unit for these Ecological Landscape Analysis reports.
Ecological land classification A classification of lands from an ecological perspective based on factors such as climate, physiography, and site conditions. The Ecological Land Classification for Nova Scotia Volume 1 delineates ecosystems at five hierarchical scales: ecozone, ecoregion, ecodistrict, ecosection, and ecosite.

Ecological integrity The quality of a natural unmanaged or managed ecosystem in which the natural ecological processes are sustained, with genetic, species, and ecosystem diversity assured for the future.

Ecoregion The second level of the Ecological Land Classification for Nova Scotia Volume 1, and a subdivision of ecozone. Used to characterize distinctive regional climate as expressed by vegetation. There are nine ecoregions identified in Nova Scotia.

Ecosection The fourth of five levels in the Ecological Land Classification for Nova Scotia Volume 1, and a subdivision of ecodistricts. An ecological land unit with a repeating pattern of landform, soils, and vegetation throughout an ecodistrict.

Ecosite The fifth of five levels in the Ecological Land Classification for Nova Scotia Volume 1, and a subdivision of ecosections. Characterized by conditions of soil moisture and nutrient regimes. Although not mapped, the Acadian and Maritime Boreal ecosites of the province are fully described in the Forest Ecosystem Classification for Nova Scotia (2010).

Ecosystem A functional unit consisting of all the living organisms (plants, animals, and microbes) in a given area, and all the non-living physical and chemical factors of their environment, linked together through nutrient cycling and energy flow. An ecosystem can be of any size – a log, pond, field, forest, or the Earth's biosphere – but it always functions as a whole unit. Ecosystems are commonly described according to the major type of vegetation, such as a forest ecosystem, old-growth ecosystem, or range ecosystem. Can also refer to units mapped in the DNR Ecological Land Classification system.

Ecozone The first of five levels in the Ecological Land Classification for Nova Scotia Volume 1. Ecozones are continental ecosystems characterized by the interactions of macroclimate, soils, geographic, and physiographic features. The entire province is contained within the Acadian ecozone, one of 15 terrestrial ecozones in Canada.

Edge effect Habitat conditions (such as degree of humidity and exposure to light or wind) created at or near the more-or-less well-defined boundary between ecosystems, as, for example, between open areas and adjacent forest.
Element  A landscape ecosystem containing characteristic site conditions that support similar potential vegetation and successional processes. Elements were mapped by combining ecosections with similar climax vegetation and natural disturbance interpretations. Depending on their role in the ecosystem, elements may be described as matrix, patch or corridor.

Endangered species  A wildlife species facing imminent extirpation or extinction. A species listed as endangered under the federal or Nova Scotia endangered species legislation (NS Endangered Species Act or federal Species at Risk Act).

Even-aged  A forest, stand, or vegetation type in which relatively small age differences exist between individual trees. Typically results from stand-initiating disturbance.

Extensive land use  Lands managed for multiple values using ecosystem-based techniques that conserve biodiversity and natural ecosystem conditions and processes.

Extinct species  A species that no longer exists. A species declared extinct under federal or Nova Scotia endangered species legislation (NS Endangered Species Act or federal SARA).

Extirpated species  A species that no longer exists in the wild in Nova Scotia but exists in the wild outside the province. A species declared extirpated under federal or Nova Scotia endangered species legislation (Nova Scotia Species at Risk Act or federal SARA).

Fine filter approach  An approach to conserving biodiversity that is directed toward individual species and critical ecosystems that are typically rare or threatened. This approach is usually combined with the coarse filter approach to conserving natural ranges of habitat.

Forest management  The practical application of scientific, economic, and social principles to the administration and working of a forest for specified objectives. Particularly, that branch of forestry concerned with the overall administrative, economic, legal, and social aspects and with the essentially scientific and technical aspects, especially silviculture, protection, and forest regulation.

Frequent stand initiating  Disturbances usually occur more frequently than the average lifespan of the dominant species and are of sufficient intensity to destroy most of the existing trees, promoting a new forest within relatively short periods of time.
<table>
<thead>
<tr>
<th>Term</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Gap replacement</td>
<td>An absence of stand-initiating disturbances supports the development of a dominant overstory that is sustained through dynamic processes of canopy gap formation, understory development, and overstory recruitment. Gap formation ranges from individual tree mortality to periodic gap formation events that are rarely of a stand-initiating intensity.</td>
</tr>
<tr>
<td>Habitat</td>
<td>The place where an organism lives and/or the conditions of that environment including the soil, vegetation, water, and food.</td>
</tr>
<tr>
<td>Infrequent stand initiating</td>
<td>The time between stand-initiating disturbances is usually longer than the average longevity of dominant species, thereby supporting processes of canopy gap formation and understory development in mature forests.</td>
</tr>
<tr>
<td>Inherent conditions</td>
<td>Refers to the natural condition of ecosystems based on their enduring physical features. This is the potential condition expected in the absence of human influence.</td>
</tr>
<tr>
<td>Integrated Resource Management (IRM)</td>
<td>A decision-making process whereby all resources are identified, assessed, and compared before land use or resource management decisions are made. The decisions themselves, whether to approve a plan or carry out an action on the ground, may be either multiple or single use in a given area. The application of integrated resource management results in a regional mosaic of land uses and resource priorities which reflect the optimal allocation and scheduling of resource uses.</td>
</tr>
<tr>
<td>Intensive land use</td>
<td>Lands managed intensively to optimize resource production from sites maintained in a forested state.</td>
</tr>
<tr>
<td>Land capability (LC)</td>
<td>LC values represent the maximum potential stand productivity (m³/ha/yr) under natural conditions.</td>
</tr>
<tr>
<td>Landform</td>
<td>A landscape unit that denotes origin and shape, such as a floodplain, river terrace, or drumlin.</td>
</tr>
<tr>
<td>Landscape</td>
<td>An expanse of natural area, comprising landforms, land cover, habitats, and natural and human-made features that, taken together, form a composite. May range in scale from a few hectares to large tracts of many square kilometres in extent.</td>
</tr>
<tr>
<td>Long range management frameworks</td>
<td>A strategic, integrated resource plan at the subregional level. It is based on the principles of enhanced public involvement, consideration of all resource uses and values, consensus-based decision making, and resource sustainability.</td>
</tr>
<tr>
<td>Term</td>
<td>Definition</td>
</tr>
<tr>
<td>----------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Matrix</td>
<td>A widespread vegetation forest community which dominates the landscape and forms the background in which other smaller scale communities (patches) occur. The most connected or continuous vegetation type within the landscape, typically the dominant element. (Matrix is a fundamental feature of the “matrix, patch, corridor” concept of landscape structure).</td>
</tr>
<tr>
<td>Mature forest</td>
<td>A development class within the sequence of: 1) forest establishment; 2) young forest; 3) mature forest; and 4) multi-aged and old growth. Mature forests include multi-aged and old growth. Forests are typically taller than 11 metres, have an upper canopy fully differentiated into dominance classes, and regularly produce seed crops. Mature forests may develop over long periods, transitioning from early competitive stages where canopy gaps from tree mortality soon close, to later stages where openings persist and understories develop to produce multi-aged and old growth.</td>
</tr>
<tr>
<td>Memorandum of</td>
<td>An agreement between ministers defining the roles and responsibilities of each ministry in relation to the other or others with respect to an issue over which the ministers have concurrent jurisdiction.</td>
</tr>
<tr>
<td>understanding (MOU)</td>
<td></td>
</tr>
<tr>
<td>Mixed stand</td>
<td>A stand composed of two or more tree species.</td>
</tr>
<tr>
<td>Multiple use</td>
<td>A system of resource use where the resources in a given land unit serve more than one user.</td>
</tr>
<tr>
<td>Natural disturbance</td>
<td>A natural force that causes significant change in forest stand structure and/or composition such as fire, wind, flood, insect damage, or disease.</td>
</tr>
</tbody>
</table>
| Natural disturbance regimes | The patterns (frequency, intensity, and extent) of fire, insects, wind, landslides, and other natural processes in an area. Natural disturbances inherently influence the arrangement of forested ecosystems and their biodiversity on a given landscape. Three disturbance regimes recognized in Nova Scotia are:

**Frequent:** Disturbances which result in the rapid mortality of an existing stand and the establishment of a new stand of relatively even age. The time interval between stand-initiating events typically occurs more frequently than the longevity of the climax species that would occupy the site – therefore, evidence of gap dynamics and understory recruitment is usually absent. This regime results in the establishment and perpetuation of early to mid-successional vegetation types.

**Infrequent:** Stand-initiating disturbances which result in the rapid mortality of an existing stand and the establishment of a new stand of relatively even-age, but the time interval between disturbance events is normally longer than the average longevity of the dominant species – allowing gap dynamics and understory recruitment to evolve and become evident (eventually creating uneven-aged stands). This regime generally leads to the establishment and/or perpetuation of mid to late successional vegetation types.

**Gap replacement:** Stand-initiating disturbances are rare. Instead, disturbances are characterized by gap and small patch mortality, followed by understory recruitment, resulting in stands with multiple age classes. This regime generally leads to the establishment and/or perpetuation of late successional vegetation types.

| Old growth | Climax forests in the late stage of natural succession, the shifting mosaic phase, marked by mature canopy processes of gap formation and recruitment from a developed understory. Typical characteristics include a multi-layered canopy of climax species containing large old trees, decadent wolf trees, and abundant snags and coarse woody debris. In Nova Scotia, stands older than 125 years are classed as old growth.

| Patch | A discrete community or element nested within a surrounding landscape, which is often a matrix forest. (Patch is a fundamental feature of the “matrix, patch, corridor” concept of landscape structure.)

<p>| Pre-commercial thinning | A silviculture treatment to reduce the number of trees in young stands before the stems are large enough to be removed as a forest product. Provides increased growing space and species selection opportunities to improve future crop tree growth. |</p>
<table>
<thead>
<tr>
<th>Term</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reserve</td>
<td>An area of forest land that, by law or policy, is usually not available for resource extraction. Areas of land and water set aside for ecosystem protection, outdoor and tourism values, preservation of rare species, gene pool and wildlife protection (e.g. wilderness areas, parks).</td>
</tr>
<tr>
<td>Riparian</td>
<td>Refers to area adjacent to or associated with a stream, floodplain, or standing water body.</td>
</tr>
<tr>
<td>Road deactivation</td>
<td>Measures taken to stabilize roads and logging trails during periods of inactivity, including the control of drainage, the removal of sidecast where necessary, and the re-establishment of vegetation for permanent deactivation.</td>
</tr>
<tr>
<td>Seral stage</td>
<td>Any stage of succession of an ecosystem from a disturbed, unvegetated state to a climax plant community. Seral stage describes the tree species composition of a forest within the context of successional development.</td>
</tr>
<tr>
<td>Species</td>
<td>A group of closely related organisms which are capable of interbreeding, and which are reproductively isolated from other groups of organisms; the basic unit of biological classification.</td>
</tr>
<tr>
<td>Species at risk</td>
<td>Legally recognized designation for species at federal and/or provincial levels that reflects varying levels of threats to wildlife populations. The four categories of risk are extirpated, endangered, threatened, and species of special concern.</td>
</tr>
<tr>
<td>Succession</td>
<td>An orderly process of vegetation community development that over time involves changes in species structure and processes.</td>
</tr>
<tr>
<td>Threatened species</td>
<td>A species that is likely to become endangered if the factors affecting its vulnerability are not reversed. A species declared as threatened under the federal or Nova Scotia species at risk legislation (NS Endangered Species Act or federal SARA).</td>
</tr>
<tr>
<td>Tolerance</td>
<td>The ability of an organism or biological process to subsist under a given set of environmental conditions. The range of these conditions, representing its limits of tolerance, is termed its ecological amplitude. For trees, the tolerance of most practical importance is their ability to grow satisfactorily in the shade of, and in competition with, other trees.</td>
</tr>
<tr>
<td>Vernal pool</td>
<td>A seasonal body of standing water that typically forms in the spring from melting snow and other runoff, dries out in the hotter months of summer, and often refills in the autumn.</td>
</tr>
<tr>
<td>Term</td>
<td>Definition</td>
</tr>
<tr>
<td>---------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Vulnerable species</td>
<td>A species of special concern due to characteristics that make it particularly sensitive to human activities or natural activities or natural events. May also be referred to as “species of special concern.” A species declared vulnerable under the federal or Nova Scotia endangered species legislation (NS Endangered Species Act or federal SARA).</td>
</tr>
<tr>
<td>Wilderness area</td>
<td>A part of the provincial landbase designated under the Wilderness Areas Protection Act (e.g. Canso Barrens).</td>
</tr>
</tbody>
</table>
