The Effect of Various Cultural Treatments on the Growth and Quality of a Balsam Fir Christmas Tree Plantation

Introduction

The goal of Christmas tree growers is to produce quality trees for the least cost in the shortest period of time. Site preparation, fertilization, vegetation control and shearing are some of the cultural practices used by growers to help achieve this goal. But, how many of these treatments are required to produce quality trees? To help answer this question for old field sites, a trial was established on Mount Thom, Pictou County in 1988.

Methods

Plantation Establishment and Treatment Description

The trial was established on an old-field at Mount Thom, Pictou County. This site is located on a Kirkhill soil (Webb, 1990), a well drained, medium-textured, silt-loam of glacial till origin. The vegetation cover consisted of grass (Gramineae sp.) (100%), goldenrod (Solidago sp.) (60%) and strawberry (Potentilla sp.) (5%). The experimental area was divided into 8 blocks. All blocks were planted May 3, 1988, with

---

%'s add to over 100% because of vegetation layering.
2+2 bare root balsam fir (Abies balsamea (L.) Mill.) at 1.8 X 1.8 m spacing. During the first 2 years, trees which died were replaced, however results in this report are based on the measurements of “original” trees planted in 1988. Shearing began when the trees reached 1.5 to 1.8 metres tall (Christmas Tree Council of N.S. et al, 1987); earlier if they started to lose their desired shape. Butt pruning, of approximately 30 cm, to the first good branch whorl was carried out when the trees had attained sufficient foliage\(^3\). Three cultural treatment regimes; Fertilizing (F), Herbiciding (H), and Liming (L) in various combinations were assigned to these blocks (Table 1).

### Lime Treatment

Soil samples were collected and analyzed for pH to determine how much lime was required to raise the pH to 6.0. The areas were then rotovated three times, with lime added after the second pass and mixed into the soil with the third rotovation. At this time a cover crop of bluegrass (Poa pratensis Linn.) and “Dutch White” clover (Trifolium repens Linn.) was established. This treatment was carried out during May 1987.

### Herbicide Treatment

The herbicide treatment (H) consisted of an annual application from 1987 to 1994. All treatments were applied in bands along the planting rows. The first treatment was applied before planting, using Vision\(^4\), in the fall of 1987. Subsequently, Vision\(^5\) was applied in 1988 and 1989, Simazine in 1990 and Velpar\(^6\)L\(^1\) from 1991 to 1994. In addition, a treatment of Lontrel\(^6\) was required in 1992. The untreated strips between the trees were mowed as required, sometimes as often as 3 times per year.

### Fertilizer Treatment

Fertilizer (F) was applied in a ring beneath the outermost foliage (drip line) of each tree, beginning 2 years after planting. Initially, it was applied at 2 ounces per tree, but in 1991-92, the fertilizer dose was based on tree height and in 1993-94, on foliar analyses. Due to lower foliar nutrient levels, the un-herbicided blocks received higher rates of fertilizer than herbicided blocks (Appendix I).

---

2+2 represents a 4 year old seedling which spent 2 years in a nursery seedbed followed by 2 years in a nursery transplant bed.

\(^3\) For a review of shearing techniques, the reader is directed to the video “Shearing Balsam Fir”, available by advance request, from the Nova Scotia Department of Natural Resources Education and Publication Services, Truro, Nova Scotia.

Data Collection

In 1992, 5 years following plantation establishment, measurements were carried out on unsheared trees in all treated blocks. Two sampling methods were used. First, the "original" unsheared trees were systematically sampled to determine total tree height, leader length and root collar diameter. Secondly, 5 to 10 "original" unsheared codominant trees were selected from each treatment and detailed measurements, relating to tree-foliage density, were recorded to further identify treatment effects (Figure 1).

In 1994, seven years following establishment, another sample of "original" (sheared and unsheared) codominant trees was taken to estimate "years to harvest" and "potential density at harvest". In addition, photographs of trees of average height and crown volume were taken.

Current costs (1994) of each treatment and expected average revenues were provided by one of NSDNR's Christmas tree specialists.

Figure 1. Measurement locations for foliage-density related factors

---

Foliage density at time of harvest and years to harvest were estimated by a Christmas tree specialist and a research technician.
Five Years after Planting

Growth Comparison

Five years following planting, the total height, total leader length and root collar diameter of the unsheared trees generally fell into two groups. Trees in herbicided blocks (FHL, FH, HL, H) showed significantly greater growth than those not herbicided (F, C). Treatment with herbicides resulted in average total height, total leader lengths and root collar diameters, at least 40% greater than those in the fertilized block (F) and over 80% greater than in the control block (C) (Table 2, Figure 2). For example, the average total height of trees receiving only herbicide (H) was 1.3 metres compared to 0.6 m for the control. The addition of lime (HL) and fertilizer (FHL and FH) did not significantly increase leader length, total height and root collar diameter (Table 2). Crown volume, on the other hand, was significantly affected by the addition of fertilizer in the herbicided blocks (Figure 2). The average crown volume of the herbicided and fertilized trees (FHL, FH) was roughly double that of trees which received only herbicide (HL, H) and 4 times that of non-herbicided trees (F, C) (0.87 vs 0.45 vs 0.19 m³).

Figure 2. Effect of various combinations of treatments on the total height, leader length, root collar diameter and crown volume of balsam fir Christmas trees, five years following planting and before shearing.
Foliage Density Measures

The effects of herbiciding, fertilizing and liming on average internode length, internode branch length, branches per internode, and the number of lateral buds and terminal buds generally fell into 3 groups (Table 3). These measures were highest for trees that were both fertilized and herbicided (FHL, FH), intermediate for herbicided trees (HL, H), and lowest for non-herbicided trees (F, C). The lack of response in the fertilizer-only trees is attributed to competing vegetation, especially grass, taking up the fertilizer instead of the crop trees. Expressed in terms of percent, trees that were both herbicided and fertilized had average internode lengths, branch lengths and number of internode branches 40-170% greater than for herbicided-only trees and 60-600% greater than non-herbicided trees. Adding lime to trees that were herbicided and fertilized, resulted in further gains but only in respect to internode length and number of branches per internode.

No significant differences were found between any of the treatments for number of branches per whorl, needle length and age of oldest needles retained by the tree.

Table 3. Effect of cultural treatments on various measures of foliage density of codominant balsam fir trees 5 years after planting.

1 Number of buds contained in the terminal bud unit, including terminal and subterminal buds.
Seven Years after Planting

By 1994, seven years following planting, most trees receiving herbicide treatments had been sheared twice, while most trees in the fertilized only and the control treatments were not yet large enough for shearing.

Foliage Density

Foliage density, projected to time of harvest, was visually estimated in December of 1994. Sample co-dominant trees were categorized as having either light, medium, or heavy foliage density. Figure 3 illustrates the average foliage density by treatment. Trees receiving herbicide (H, HL, FH, FHL) were projected to have the highest foliage densities with 78 to 100% graded as medium to heavy (Table 4, Figure 3). The addition of lime and fertilizer did not appear to further improve density. On the other end of the scale, all trees in the fertilized-only (F) and control (C) treatments were projected to have light foliage density.

The effect of the various treatments on average foliage density is illustrated in photographs taken in January of 1995, 7 years after planting (Figure 4). The pictures show the controls and “fertilize only” trees were the shortest and had the lowest foliage density while the herbicided and fertilized trees were the tallest and most dense.

1 Estimates based on examining trees 7 years after planting.
2 Rotation age - estimated number of years (since planting), to reach a harvestable height of 6 - 8 feet.
Figure 3. Estimated average foliage density and age at harvest. Estimates based on trees 7 years after planting. Harvest age is the estimated number of years (since planting), to reach a harvestable height of 6-8 feet.
Figure 4. Photographs, taken 7 years after planting, depicting average trees by treatment.
Years to Harvest

In addition to foliage density, an estimate was made of the number of years (since planting) to harvest based on a harvest height of 6 - 8 feet (Table 4 and Figure 3). All trees Fertilized and Herbicided (FHL, FH) are projected to be harvestable by 11 years, and over half of the trees by 9 years. All herbicided (HL, H) trees should be harvestable by 12 years with 75% ready for market by age 11. Trees which did not receive herbicide treatments (F,C) are projected to have the longest rotation at 12 to 13 years.

The addition of lime (FHL and HL) appears to slightly reduce the average rotation age and increase the portion of the trees harvestable at younger ages.

Costs and Revenues

All treatments carried out for this trial are documented by block number in Appendix I. The current (1994) treatment costs\(^6\) and sale revenues\(^6\) (Appendix II), are also included along with these same values discounted at 5%. Current net revenues, without discounting, ranged from $1.15 per tree for trees Fertilized (F) to $4.38 for trees Fertilized and Herbicided (FH).

To compare the before tax economic returns resulting from the treatments over time, the closing balance of a 14 year investment on one acre was examined (Appendix I). It was assumed that each treatment started with a bank account of $4,000 and monies were taken from this account as treatments were carried out, and added as revenues accrued. The interest was calculated daily and the bank accounts were assumed to earn an annual rate of 5%. Figure 5 shows how each of the Christmas tree bank accounts would change over time. At the end of this time, a non Christmas tree account would have a value of $7,923. The only treatment with a lower return was the Fertilizer (F) block which was projected to earn $7,792. The highest bank balances were achieved by treatments involving herbicide and fertilizer: $10,579 (FHL) and $11,636 (FH).

Another way to compare treatments is by looking at their Internal Rate of Return (Gunter et al, 1984) which is the interest rate at which one is indifferent between investing in a project and leaving one’s money in the bank. Figure 6 shows the internal rate of return for each treatment, which uses the same parameters as the previous comparison, i.e. an opening bank account of $4,000 dol-

---

\(6\) Costs and revenues were obtained from various industry sources and are based primarily on cultivated natural stands rather than old field plantations. Costs not included were overhead, rental of land, cull trees, monitoring for pests, corrective pruning and soil/foliar analyses.
Figure 5. A comparison of the return on $4,000 invested in a bank account versus Christmas trees grown according to six different treatment regimes, assuming an interest rate of 5%.
The major findings of a trial undertaken to determine the effects of individual and combined treatments of Fertilizer, Herbicide and Lime on the growth, quality and costs of producing balsam fir Christmas trees on an old-field site are as follows:

1. Vegetation management using herbicides reduced rotation age and increased height growth, foliage density, and internal rate of return.

Herbicated trees (HL, H) were (Table 5):

- 73% taller,
- 79% more frequently projected to have medium-heavy density foliage at rotation; had:
  - 137% greater crown volume,
  - 86% more branches per internode,
  - 8% shorter rotation age, and had a
  - 2.7% higher average internal rate of return

than trees not herbiced (F, C).

### Table 5. Summary of average growth, foliage density, rotation ages and internal rate of return and their % increases by treatment.

1. Measurements taken before shearing.
2. Projections based on 6'-8' crop height (Table 4).
3. % of trees estimated to have medium to heavy foliage density at rotation (6'-8' tall).
4. % difference is based on (HFL-HF) x 100.
2. The addition of fertilizer further reduced rotation age and increased height growth, foliage density and internal rate of return. Herbicided and Fertilized trees (HFL, HF) were:

- 15% taller,
- 16% more frequently estimated to have medium-heavy density at rotation, had
- 93% greater crown volume,
- 123% more branches per internode,
- 15% shorter rotation age, and had a
- 3% higher average internal rate of return

than herbicided trees (HL, H).

3. Although less dramatic, the incorporation of lime resulted in decreased rotation age and increased density. Herbicided, Fertilized and Limed trees (FHL) were:

- 15% greater in crown volume, had
- 52% more branches per internode, and a
- 2% shorter rotation age,

than fertilized and herbicided (F, H) trees.

4. Based on projections to rotation, the combination of herbicide and fertilizer was the most cost effective treatment in producing balsam fir Christmas trees in a plantation located on an old-field site at Mount Thom, Nova Scotia.
