residual effects of the Project will be determined using the criteria, based on federal and provincial EA guidance (Table 13.2).

The expectation for, and significance of, residual effects determines the need for a monitoring and/or follow-up program.

13.2 Effects Assessment

Effects and mitigation measures related to each VEC are described below. Potential effects of the Project on the identified VECs are further analyzed in Tables 13.4 to 13.6 to identify and evaluate the significance of residual effects, based on the criteria listed above. Mitigation measures are also summarized.

Accidents and malfunctions are considered for each phase.

13.2.1 Species of Conservation Interest

It is widely acknowledged that wind energy development can have a suite of potential direct and indirect impacts on terrestrial fauna (Arnett et al. 2007; Kuvlesky, Jr. et al. 2007). General construction activities within and adjacent to watercourses and water bodies, can affect aquatic fauna and habitat. The extent and magnitude of these impacts can vary with the stage of the Project but are present for all phases.

During the site preparation and construction phases of wind energy projects, potential impacts to SOCI will be related to:

- sensory disturbance;
- habitat loss/alteration and/or fragmentation, and
- effects on fish passage/migration; and
- mortality.

**Sensory Disturbance**

Sensory disturbance to fauna SOCI may occur from a variety of anthropogenic sources. For wind energy projects, disturbance impacts are typically most significant during the construction phase, which involves increased presence of on-site personnel, vehicles, and heavy equipment (Helldin et al. 2012). Avoidance impacts related to the construction phase have been reported for large mammals in two cases [e.g., Rocky Mountain Elk (Cervus elaphus) (Walter et al. 2006) and wolves (Álvares et al. 2011)], but in both cases the effects were temporary and subsided once construction was completed. It is expected that avoidance or displacement effects related to the site preparation and construction phases of the Project will not persist in the long-term.

It is also important to distinguish wind energy facility roads from high-use motorways in regards to sensory disturbance. Many of the documented effects of roads are related to avoidance due to traffic noise (Forman and Alexander 1998). The magnitude of such effects will be greatly reduced in the context of this wind energy development, as road traffic will be minimal (maintenance vehicles during operations) and limited.

Sensory disturbance during the operations and maintenance phase of the Project will be limited to the presence of on-site personnel conducting maintenance on Project infrastructure. Although literature on the topic is sparse, most evidence suggests that in general, terrestrial wildlife are not adversely effected by operating wind turbines. It was determined that a population of elk in Oklahoma, for example, did not change their home range or experience reduced dietary quality within an operating wind power development (Walter et al. 2006). It is therefore unlikely that...
ungulates in the Project site, including White-tailed deer and potentially Mainland moose, will be affected. Likewise, the small mammal community at a wind energy development in Spain was demonstrated to be unaffected by turbine operations (de Lucas et al. 2005).

Impacts to fauna SOCI during the decommissioning phase of the Project will be similar to those experienced during the site preparation/construction phase (Helldin et al. 2012). Namely, sensory disturbance due to the increased presence of on-site personnel and the operation of heavy equipment may elicit temporary displacement/avoidance behaviours in mobile wildlife species. No sensory disturbance impacts are expected for fish SOCI.

**Habitat Loss/Alteration**

Although the permanent footprint of a wind energy facility is generally estimated to be just 5 to 10% of the Project site (Arnett et al. 2007), there is the potential that significant habitat elements for certain fauna SOCI may altered/removed during site preparation activities, such as clearing, for turbine pads and access roads. However, the effects may be negligible if the habitat is in adequate supply in the general area surrounding the Project site (Arnett et al. 2007). Since the Project footprint represents approximately 2.5% of the Project site area and habitat types at the Project site are common in the surrounding landscape, the effects of habitat loss/alteration on terrestrial fauna SOCI will be minimized.

The construction of roads has a variety of well-documented, adverse effects including fragmentation of otherwise continuous segments of suitable habitat and restriction of movement of individuals between habitat patches (Trombulak and Frissell 2000, Eigenbrod et al. 2008), avoidance of adjacent habitat, increased access for hunters/poachers (Brody and Pelton 1989; Helldin et al. 2012), which can potentially result in increased mortality of certain wildlife species while also facilitating the expansion of interspecific competitors (Beazley et al. 2004) and exotic species (Trombulak and Frissell 2000). The road network will have a small footprint due to the small size of the Project, which will significantly reduce the magnitude of any potential effects. Furthermore, Project layout will incorporate an existing network of logging roads that extend throughout the site and throughout the surrounding landscape.

Potential effects to fish SOCI and associated habitat during the site preparation and construction phases the Project would be primarily related to the construction and upgrading of access roads and the installation of crossing structures where roads intercept watercourses. Vegetation clearing along banks and land adjacent to watercourses could result in significant habitat degradation for fish and other aquatic biota if appropriate mitigation techniques are not employed. The alteration or removal of riparian vegetation may result in bank instability and erosion, leading to sedimentation of the water body and degradation of water quality.

Removal of overhanging vegetation from stream banks decreases shade/cover for fish resulting in increased vulnerability to predators and potentially in increased localized water temperatures. Likewise, the removal of instream cover, such as coarse woody material or edge habitat (e.g., undercut banks) may have a similar effect on fish habitat. Coarse woody material also provides habitat for aquatic invertebrates. Alterations to channel morphology and interference with sediment transport may also lead to fish habitat modification/degradation (MTO 2009). Many effects to fish
habitat can be mitigated through thoughtful planning and the incorporation of standard mitigation and BMPs (refer to Section 4).

The potential effects of the Project on fauna SOCI habitat during the operational phase are likely to be minimal. Aside from surface disturbance and the possible removal of regenerated vegetation, decommissioning will not include additional habitat loss/alteration. Therefore, the impacts to fauna SOCI during this phase of the Project are not expected to be significant in magnitude or long-term in duration.

**Effects on Fish Passage/Migration**
Lack of consideration for fish migration/passage during the design of crossing structures and/or appropriate installation techniques may also lead to a number of effects on Atlantic salmon. These effects typically manifest as modifications or barriers to fish movement through the affected watercourse. Barriers to fish passage include velocity barriers, alteration of the stream gradient and insufficient flow/depth (MTO 2009).

Many effects to fish passage can be mitigated through thoughtful planning and the incorporation of standard mitigation and BMPs (refer to Section 4.0).

**Collision Mortality**
Increased vehicle and heavy equipment traffic during all phases of the Project may result in collisions with terrestrial wildlife. It is expected that these collision events will be minimized by the implementation of safe work practices (e.g., strict adherence to speed limits, obeying all warning signs, etc.). Collisions, should they occur, will be infrequent and will not have a significant effect on population levels.

**General Mitigation Measures**
The following specific mitigative measures will be implemented to avoid and mitigate any potential effects on SOCI:

- Minimization of the footprint of physical disturbance by:
  - Alignment of access roads with existing roads and logging trails, wherever possible.
  - Where the aforementioned is not possible, designing and constructing access roads to avoid environmentally sensitive habitats, where possible, and ensuring the most efficient means to access turbines is achieved.
  - Maintenance of a buffer around sensitive habitats such as watercourses and wetlands, where possible.
  - Minimizing routine vegetation clearing:
    - clearing of land only if required for construction area footprint;
    - restoration of areas of disturbance where possible, post construction; and
    - siting construction compounds in/on non-sensitive areas.
- Completion of a comprehensive schedule and determination of timelines to efficiently complete Project activities within the shortest time frames possible.
Species-Specific Mitigation
Desktop and field analyses for fauna SOCI revealed several species that have the potential to occur at the Project site. Addressing the potential impacts of the Project on these species will require species-specific mitigation techniques, as described below:

Fisher:
- Project activities will be planned to minimize disturbance to Fisher habitat at the Project site, particularly in mature, mixed wood stands featuring large, hollow trees (suitable for denning) and areas of continuous canopy cover (Gilbert et al. 1997).

Mainland moose:
- Project personnel will report any evidence of Mainland moose to NSDNR.

Monarch:
- Should large congregations of Monarchs be found at the Project site, Project activities in the area should cease until the migrating group has left the Project site. This is most likely to occur in late summer, prior to the fall migration.

Wood turtle:
- Based on recommendations outlined in the document ‘Protecting and Conserving Wood Turtles: A Stewardship Plan for Nova Scotia’ (MacGregor and Elderkin 2003), and the “NS Transportation and Public Works Generic Environmental Protection Plan for the Construction of 100 Series Highways” (NSTPW 2007), the following general procedures will be implemented to ensure the protection of Wood turtles:
  o Any turtles found will be relocated outside of the construction zone, along the same habitat corridor in the direction of travel the turtle was originally oriented and preferably upstream within the same riparian habitat corridor (< 400 m).
  o Any sightings of wood turtle will be reported to the NS Wood Turtle Recovery Team at 1-866-727-3447.
  o Adequate, permanent buffers of vegetation will be left around important Wood turtle habitat. If necessary (i.e., in the event that Wood turtles are confirmed at the site), an appropriate mixture of shrubs and trees shall be planted to create a buffer.

Fish SOCI (Atlantic Salmon, American Eel, Striped Bass):
- The siting, design, installation and decommissioning of all crossing structures will incorporate ongoing consultation with DFO, and NSE, and will avoid areas of sensitive habitat and ensure that fish passage is maintained;
- Additional mitigation for the protection of fish habitat will be ensured through the NS watercourse alteration permitting process.

13.2.2 Avifauna
The effects of a wind farm on birds are variable and depend on factors such as the development design, topography of the area, habitats affected, and the bird community in the wind farm area (Drewitt and Langston 2006). Although some effects are related to construction (e.g., habitat alteration), most potential effects on avifauna are mainly related to operation and may include:
- habitat loss/alteration;
- mortality resulting from direct collision; and
- sensory disturbance.

**Habitat Loss/Alteration**

Habitat alterations resulting from the site preparation and construction phases of wind energy developments have the potential to impact bird populations either directly or indirectly (Arnett et al. 2007). However, impacts are considered less severe than those from other energy extraction developments such as oil and gas exploration because the disturbance is limited to the construction footprint (i.e., turbine pads, roads, associated buildings, etc.) (Kuvlesky et al. 2007). The magnitude of these impacts, however, may be magnified if the disturbed area contains sensitive plant communities that provide important habitat to local bird populations (Kuvlesky et al. 2007). Altered landscapes can potentially lead to displacement of species with sensitive habitat requirements (Arnett et al. 2007). Site clearing and preparation may involve the removal of key habitat features, such as standing deadwood, mature trees, or shrub cover required as foraging and/or breeding habitat for certain bird species.

Mature forest, for example, is present at the Project site and its removal may displace bird species into other mature stands in the general area. In addition, three of four turbines will be located in cutovers. Surface disturbance is greater in the construction phase than in the operational phase because large right of ways need to be created to accommodate large construction equipment and transport vehicles (Arnett et al. 2007). It can therefore be assumed that impacts associated from direct habitat alteration are greatest in the short-term, except when key habitat features are permanently removed. Depending on the availability of nearby alternative habitat, habitat alterations associated with wind energy infrastructure may have detrimental effects on local bird populations. The landscape of the Project site and immediately surrounding area features forest stands that would appear to provide suitable alternative habitat to bird species displaced due to habitat alteration at the Project site.

**Collision Mortality**

The most overt potential effect of the Project on birds is direct mortality resulting from collision with Project infrastructure, namely turbine blades, during the operational phase. Most evidence suggests that mortality levels resulting from turbine collisions are low (EC et al. 2012) although many studies do not adequately incorporate carcass removal by scavengers into mortality estimates. In a review of night migrant fatalities at wind farm sites in North America, Kerlinger et al. (2010) found fatality rates of less than one bird/turbine/year to approximately seven birds/turbine/year, even with corrections made for scavenger removal and searcher efficiency. Furthermore, multi-bird fatality events, in which more than three birds were killed at a turbine site in a single night, were found to be rare and may have been related to lighting and/or inclement weather (Kerlinger et al. 2010).

Collision risk is greater on or near areas used by large numbers of foraging or roosting birds or in important migratory flyways (Drewitt and Langston 2006). In Canada, passerines account for 70% of all fatalities, with most occurring during the fall migration season (EC et al. 2012). The probability of raptor collision with wind turbines depends on the species, turbine height, and local topography (de Lucas et al. 2008). Collision risk can therefore be greatly reduced by incorporating knowledge of the avifauna into the design and placement of wind power infrastructure.
In summary, available research suggests that the probability of large-scale fatality events occurring at wind farms is extremely low (Kerlinger et al. 2010) and the observed mortality caused by wind energy facilities is low compared to other sources of human caused bird mortality (i.e., buildings, communications towers, vehicles, etc.) (Kingsley and Whittam 2005). Baseline information gained from avian surveys can be combined with site specific considerations to greatly reduce the risk of bird collisions.

**Sensory Disturbance**

Sensory disturbance to birds can occur during the construction, operational, and decommissioning phases of wind power projects, and can be caused by the increased presence of personnel, vehicle movement, operation of heavy equipment, and the operation of the turbines themselves (Drewitt and Langston 2006). It is thought that disturbance to birds may have a greater population impact than collisions, although research is lacking in this area (Kingsley and Whittam 2005). Primary concerns with regards to sensory disturbance are related to displacement and potential effects on key physiological processes such as breeding.

Some studies have shown that birds will exhibit avoidance behaviours post-construction, leading to a variable degree of displacement from previously used habitat (reviewed in Drewitt and Langston 2006) which essentially amounts to habitat loss. In most cases, such displacement is on the scale of tens to hundreds of metres, which can lead to localized changes in bird densities (Leddy et al. 1999; Pearce-Higgins et al. 2009). However, while birds may avoid specific sites, the evidence does not suggest that birds abandon the general area as a whole. Other research indicates that the presence of wind turbines has no effect on the distribution of the bird community (Devereux et al. 2008) and birds may habituate to the presence of operating wind turbines (Madsen and Boertmann 2008). The tolerance to Project related disturbance may be species specific but may also be related to the availability of alternative habitat (Kingsley and Whittam 2005). Thus, careful site selection of turbines to avoid any unique habitat types will alleviate some disturbance and/or displacement effects, especially during the operational phase of the Project.

**General Mitigation Measures**

The following mitigative measures will be implemented to avoid and mitigate any potential effects on avifauna:

- Where possible, clearing of site vegetation will be conducted outside of the breeding and nesting season for birds (April to August). If this is not possible, a mitigation plan will be developed in consultation with NSDNR and CWS prior to clearing activities.
- Surveys for raptor nests will be completed prior to any clearing activities occurring during the main nesting season for this group (mid-February to mid-May).
- Use of lighting during construction and on turbine hubs and blades will be limited to minimum levels while still meeting requirements of Transport Canada.
- There will be no general lighting at the Project site. Lighting will only be used when technicians are working on-site.
- Where possible, placement of Project infrastructure in habitats significant to bird species (as identified during avian surveys) will be avoided. These include wetlands, mature forests, and areas with large, hollow trees.
Post-construction monitoring will be implemented under direction from NSE and in consultation with CWS and NSDNR to monitor for significant mortality trends.

**Species-Specific Mitigation**

Bird surveys identified three species that are listed under either SARA or NS ESA. Addressing the potential impacts of the Project on these species will require species-specific mitigation techniques, as described below:

**Canada Warbler:**
- Project activities will avoid and/or minimize disturbance to Canada Warbler nesting habitat, including mature forest habitats with well-developed shrub layers and wetland habitats, and especially treed and shrub swamps.
- An increased buffer distance will be maintained between turbine locations and delineated wetland edges where evidence of breeding was identified during surveys.

**Eastern Wood-Pewee:**
- Project activities will avoid and/or minimize disturbance to Eastern Wood-Pewee nesting habitat, including areas of low canopy cover, near or within large deciduous or mixed wood forest stands.

**Olive-sided Flycatcher:**
- Project activities will avoid and/or minimize disturbance to Olive-sided Flycatcher resources and nesting habitat, including tall trees or snags within clearings (required for perching and foraging), especially near wetlands or edges of mature coniferous forest stands.

### 13.2.3 Bats

The installation of wind turbines has the potential to impact bats both directly and indirectly (Arnett et al. 2007). Although some effects are related to construction (i.e., habitat alteration), most potential effects on bats are mainly related to operation and may include:

- habitat loss/alteration;
- mortality resulting from direct collision and/or barotrauma; and
- sensory disturbance.

The significance of these impacts at the population level depends on a number of biotic and abiotic variables, including the number of individuals affected and the stability of the population, season, physiologic condition of the individuals affected, and weather factors.

**Habitat Loss/Alteration**

Habitat alterations, including vegetation clearing and soil disruption (NRC 2007) resulting from the site preparation and construction phases, may impact bats (Arnett et al. 2007). The removal of trees during the site clearing and preparation phases can be especially detrimental, particularly to those bat species which use trees as roosting habitat (Arnett et al. 2007).
Some studies, however, suggest that habitat changes related to wind power developments may in fact create benefits to bats by increasing cleared areas and creating access roads, both of which can be used by bats as foraging habitat (as cited in Arnett et al. 2007; Kunz et al. 2007a). In relation to this, small-scale disturbances, including creating small cutblocks or small scale access roads through forested habitat, have been shown to stimulate an increase in bat activity relative to previous years (Grindal and Brigham 1998). It is important to note, however, that increased edge habitat due to forest clearing may subsequently increase the risk of mortality by virtue of attracting bats to the area of the operating turbine (Kunz et al. 2007b).

Mortality
Mortality of bats is a potential effect during the operational phase of wind energy projects. Necropsy of recovered carcasses found that the cause of death for bats killed at wind-energy facilities is an indiscernible combination of direct collision with the turbine blades and barotrauma (Grodsky et al. 2011), although more recent pathological research has found that traumatic injury is the major cause of bat mortality at wind farms and that post-mortem artifacts may manifest themselves as pulmonary barotrauma lesions (Rollins et al. 2012). Barotrauma is characterized by a drop in atmospheric pressure along the top of a rotating turbine blade, which causes thoracic, abdominal, and pulmonary injury to bats when passing through the low pressure area (Baerwald et al. 2008).

Much of the established literature has not attempted to elucidate the causes of bat mortality but has instead reported on the magnitude of mortalities. In Canada, EC reports that bat fatalities outnumber bird fatalities (EC et al. 2012). This causes concern as bats are long-lived and have low reproductive rates (Arnett et al. 2007).

Research suggests that migratory tree-roosting species suffer the highest fatalities at wind farms (Kunz et al. 2007a; Kuvlesky et al. 2007; Cryan and Barclay 2009), although deaths of Tri-colored bats constituted 25.4% of total bat fatalities at wind facilities in the eastern United States (as cited in Arnett et al. 2007). Migratory species, including Hoary bat, Eastern red bat, and Silver-haired bat, accounted for 71% of 2,270 bat fatalities recorded at wind energy facilities across Canada between 2006 and 2010 (EC et al. 2012). Most bat fatalities are reported in the late summer months (Johnson 2005) coinciding with the start of swarming and autumn migration (Arnett et al. 2007; EC et al. 2012). Periods of high mortality may therefore be linked with the timing of large-scale insect migrations when bats feed at altitudes consistent with wind turbine heights (Rydell et al. 2010). It has been found that bat fatalities increase exponentially with wind tower height, with turbine towers 65 m or taller having the highest fatality rates (Barclay et al. 2007). This hypothesis is also supported by the findings of Horn et al. (2008), who reported that bats were not being struck by turbine blades when flying in a straight line en route to another destination, but were struck while foraging in and around the rotor-swept zone of the turbine.

Temporal variation in bat activity and subsequent fatality rates can be influenced by weather variables, as well as the characteristics of the facility (Baerwald and Barclay 2011). Although bats exhibit species-specific responses to environmental variables (Baerwald and Barclay 2011), in general they appear to be more active when wind speeds are low, which increases the risk of collisions with rotating turbine blades (Arnett et al. 2007) and mortality resulting from barotrauma.
Sensory Disturbance
Increased human presence may also disturb roosting bats (Arnett et al. 2007), but it is unknown if this disturbance is sufficient to disrupt normal behaviour or physiology. Sensory disturbance to bats is most likely during the site preparation/construction and decommissioning phase of the Project, during which the presence of on-site personnel and equipment will be the highest. During hibernation, bats are sensitive to human presence, and human intrusion into hibernacula can lead to increased arousals leading to a premature depletion of fat reserves (Thomas 1995). Siting wind-energy facilities away from hibernacula is therefore recommended in the design phases of these projects.

It is unknown if noise associated with the operational phase of wind energy projects has any measureable effect on bats, although it is thought that bats may become acoustically disoriented by the low-frequency noise emitted from rotating turbines (Kunz et al. 2007a). Bats have been shown, experimentally, to avoid foraging in areas with intense, broadband noise (Schaub et al. 2008), however this research was not conducted in the context of wind-energy development and other studies indicate that bats have been shown to forage in close proximity to operational turbines (Horn et al. 2008).

General Mitigation Measures
The following specific mitigative measures will be implemented to avoid and mitigate any potential effects on bats:

- Use of lighting during construction and on turbine hubs and blades will be limited to minimum levels while still meeting requirements of Transport Canada.
- Where possible, placement of Project infrastructure in habitats significant to bat species will be avoided. These include hibernacula, wetlands, and lands directly adjacent to open bodies of water.
- Post-construction monitoring will be implemented under direction from NSE and in consultation with CWS and NSDNR to monitor for significant mortality trends.

13.3 Environmental Effects Analysis
The following tables (Tables 13.4 to 13.6) identify and evaluate the significance of residual effects for each phase of the Project on each VEC. Accidents and malfunctions are also analyzed. As most of the mitigation is the same for avifauna and bats, these VECs are considered together to decrease repetition.

**General Mitigation Measures**
- Implementation of the EPP.
- Minimize the footprint of physical disturbance to the extent possible.
- Avoid disturbing sensitive/significant habitats during construction to the extent possible.
- Minimize vegetation clearing, wherever possible.
- Prompt restoration of cleared areas post-construction.
- Maintain efficient timelines to complete Project activities within the shortest amount of time possible.

**Species-specific Mitigation**
- Avoid mature, mixed wood stands which may feature suitable denning trees for Fisher.
- The EPP for the Project will require Project personnel to report any Mainland moose sightings to NSDNR.
- Should large congregations of Monarchs be found at the Project site, Project activities in the area should cease until the migrating group has left the Project site.
- Leave adequate, permanent buffers of vegetation around important Wood turtle habitat.
- In the event that Wood turtles are confirmed at the site, an appropriate mixture of shrubs and trees will be planted to create a buffer.
- Any wood turtles found will be relocated outside of the construction zone (as per guidelines outlined in MacGregor and Elderkin 2003, and NSTPW 2007).
- Report any sightings of wood turtle to

13.4 Follow-up Measures
A potential residual effect for avifauna and bats was noted in Table 13.5. The potential effect of collisions and/or fatalities to these VECs will be addressed in post-construction monitoring programs that will be implemented to assess the effects of the operation of the proposed wind farm.

14.0 EFFECTS OF THE ENVIRONMENT ON THE PROJECT

Environmental factors that have the potential to have damaging effects on wind turbines include:

- Extreme wind (typically associated with hurricanes);
- Hail;
- Ice storms/ice formation;
- Heavy snow;
- Lightning; and
- Fire.

The primary mitigative measure employed during the construction and operation of the Project will be to educate and train site personnel. Environmental and safety orientations will be conducted prior to the start of construction and all staff will be informed of the potential effects of the environment on the Project. Staff responsible for the operation and maintenance of the Project will be trained on the design and operation of the turbine, including applicable operating procedures, safety protocols and evacuation plans.

Modern wind turbines are equipped with a number of mechanisms to reduce damage caused by extreme weather and are designed to shut down when certain thresholds are detected (CanWEA 2011). Further, best practices and industry standards will be applied to the operation of the Project to manage risks of damage from extreme events. Table 14.1 demonstrates potential effects resulting from environmental events and the mitigation associated with each.

| Heavy snow                | Damage to turbines.           | • Turbine design equipped to shut down |

Table 14.1 Effects of Environmental Events and Associated Mitigation
### 15.0 CUMULATIVE EFFECTS ASSESSMENT

Concerns are often raised about the long-term changes that may occur not only as a result of a single action but of the combined effects of each successive action on the environment (Hegman et al. 1999).

The cumulative effects assessment focuses only on adverse effects of the Project remaining after the application of mitigation measures (*i.e.*, only residual effects). For this Project, the only VECs identified to have a potential residual effect are avifauna and bats (*i.e.*, collision mortality). Therefore, known or anticipated activities within a 20 km radius of the Project site were reviewed to identify the potential for cumulative effects on avifauna and bats.

A search for existing or proposed wind farm developments was completed within the 20 km radius of the Project site. Two proposed projects, the Nine Mile River Community Wind Project (4 MW) and Chebucto-Pockwock Community Wind Project (10 MW), are located approximately 12 km to the north and 19 km to the southwest, respectively, which have the potential to act cumulatively with this Project. Both wind projects are of relatively small size, therefore the potential for cumulative effects related to avifauna and bat mortality as a result of both projects are considered not significant.

17.0 CONCLUSIONS

In accordance with “A Proponent’s Guide to Wind Power Projects: Guide for Preparing an Environmental Assessment” (NSE 2012a), the studies, regulatory assessments, and VEC evaluations described within this document have been considered both singularly and cumulatively.

The results indicate that there are no significant environmental concerns or impacts that may result from the Project that cannot be effectively mitigated or monitored.

Best practices and standard mitigation methods will be implemented during all phases of the Project, to ensure methods and practices are comprehensive and are adhered to. Furthermore, an EPP will be developed and communicated to all employees working on the Project.

The proposed capacity of the turbines will produce enough energy to power 2,700 households and will contribute to reaching Nova Scotia’s renewable energy commitments.
