Many studies in mice (138, 206, 207, 232–234) and rats (232, 235–239) have described differences displayed between two (or more) animal strains to a natural hormone or EDC. Often these differences can be traced to whether a strain is inbred or outbred. Genetically diverse strains are generally found to be more sensitive to estrogens (206). Importantly, well-controlled studies demonstrate that strain differences in response to estrogen treatment may be organ dependent or may even differ between levels of tissue organization within the same organ. For example, the Sprague-Dawley rat is more sensitive to ethinyl estradiol than other strains when measured by uterine wet weight. However, when other endpoints were measured, *i.e.* height of cells in the uterine epithelium, the Sprague-Dawley rat was indistinguishable from the DA/Han rat; instead, the Wistar rat had the most heightened response (237). Additionally, there are data to indicate that strain differences for one estrogen may not be applicable for all estrogenic chemicals. In comparing the responses of DA/Han, Sprague-Dawley, and Wistar rats to other xenoestrogens, additional differences were observed including a greater increase in uterine wet weight of DA/Han and Sprague-Dawley rats but not Wistar rats after exposure to 200 mg/kg BPA; increased uterine epithelium thickness was observed in Wistar and Sprague-Dawley rats but not DA/Han rats after exposure to 200 mg/kg octylphenol (237). Attempts have been made, at times successfully, to map the differences in strain response to genetic loci (240). However, it appears that strains with differences in response that manifest in some organs do not have divergent responses in other organs, a phenomenon that is not explained by genetic differences alone. For these reasons, the NTP's recommendation that scientists use animals that are proven responsive to EDCs (2) must be observed.

4. Additional factors?

Additional factors have also been identified as influential in the ability (or inability) to detect low-dose effects in

Downloaded from https://academic.oup.com/edrv/article-abstract/33/3/378/2354852 by guest on 25 February 2019

EDC studies. Although these factors must be considered when interpreting studies and using a WoE approach, some issues that were previously identified as essential factors in the design of studies (*i.e.* route of administration) have more recently been disputed (241).

The first factor is the use of good laboratory practices (GLP) in the collection of data. When assessing the EDC literature for risk assessment purposes, the FDA and European Food Safety Authority (EFSA) have given special prominence to studies that complied with GLP guidelines, essentially giving scientific priority to industry-funded studies because that group typically conducts GLP guideline studies (33, 242). Because GLP guidelines are designed only to control data collection, standards for animal care, equipment, and facility maintenance, and they do not ensure that studies were designed properly with the appropriate controls, it has been argued that the use of GLP methods is not appropriate or required for EDC studies (69).

GLP studies are typically large, with dozens of animals studied for each endpoint and at each time point. Thus, it has been concluded that these studies are better simply because they are larger. Yet small studies designed with the use of power analysis, statistical tools that allow researchers to determine *a priori* the number of animals needed to determine significant differences based on effect size, are equally capable of detecting effects while reducing the number of animals used (69). GLP studies also typically (but not necessarily) rely upon standardized assays, which are not generally considered contemporary tools and are often shown to be incapable of detecting adverse effects on endpoints that employ modern tools from molecular genetics and related disciplines. Furthermore, some fields of EDC research have no GLP studies (243). Finally, there is no published evaluation of whether studies performed under GLP are more capable of providing accurate results. The priority given to GLP studies therefore does not appear to have been justified based on any comparative analysis. Thus, as long as studies include appropriate measures of quality assurance, they need not be performed under GLP standards to provide reliable and valuable information, and many GLP studies are inadequate to assess important and relevant endpoints. Instead, the most valuable studies consider the factors presented above, along with appropriate dose selections and choice of endpoint.

The second factor worth considering is the source of funding for studies. In several fields, significant controversy has been produced based on the results obtained from independent scientists compared with results obtained from scientists affiliated with the chemical industry (75, 76). Funding source *per se* should not dictate the outcome of a research study, but that does not mean that researchers are not subject to underlying biases. In our own WoE analyses, presented in *Sections II.C–G*, we do not discount studies merely because they were conducted with industry funds, nor do we lend higher weight to studies conducted in independent or government laboratories; if a study, regardless of funding, finds no effect of a chemical, it is given weight only if the three criteria described in *Sections II.B.1–3* (successful and appropriate negative and positive controls and appropriate choice of animal model) were met.

To perform a WoE evaluation, we identified some basic information about the chemical in question, the dose that would be considered a low-dose cutoff, and the studies in support of and against low-dose effects. We then considered whether the majority of studies found effects of low doses of a chemical on a single endpoint in question. If studies did not find low-dose effects, we considered whether they adhered to the criteria discussed above for proper design of an EDC low-dose study. In particular, we considered whether appropriate animal strains as well as positive and negative controls were used. With regard to animal strain, as discussed briefly in *Section II.B.3*, there is variability between animal strains that can significantly influence the ability to detect effects of EDCs; using insensitive strains to produce negative data cannot refute positive data in a sensitive strain. In several cases, it was easy to conclude that there was a strong case for low-dose effects because there were no studies finding no effects at low doses or because all of the negative studies were inappropriately designed. For other chemicals, a significant number of studies found effects on the endpoint being considered, but other (adequately designed) studies refuted those findings. Under those circumstances, we determined whether the findings of harmful effects came from multiple laboratories; when they did, we cautiously concluded that there was evidence for low-dose effects. Below (*Sections II.C–G*), we present five examples where a significant number of studies were available examining low-dose effects of an EDC on a single particular endpoint.

C. BPA and the prostate: contested effects at low doses?

As discussed briefly above, BPA is one of the best-studied EDCs, with more than 200 published animal studies, many of which focused on low doses (29, 31). The effects of this chemical on wildlife species have also been described in detail (28). BPA is found in a myriad of consumer products, and it leaches from these items under normal conditions of use (4). It has also been regularly detected in air, water, and dust samples. The majority of individuals in industrialized countries have BPA metabolites in their urine, and trends indicate increasing expo-

Downloaded from https://academic.oup.com/edrv/article-abstract/33/3/378/2354852 by guest on 25 February 2019

sures in developing nations like China (87, 244). Although it was long suspected that most human exposures originate from BPA contamination of food and beverages, a study comparing the excretion of BPA metabolites with the length of time spent fasting suggests that there are also likely to be significant exposures from sources other than food and beverages (245). BPA has recently been shown to be used in large quantities in thermal and recycled papers and can enter the skin easily via dermal absorption (246–248). Thus, despite the large amount of information available on BPA sources, our understanding of how these sources contribute to total human exposures remains poor; these studies also point to significant gaps in current knowledge about BPA metabolism in humans (243).

BPA binds to the nuclear and membrane ER, and thus most of the effects of this chemical have been attributed to its estrogenic activity (27). However, there is evidence that it can activate a number of additional pathways, including thyroid hormone receptor, androgen receptor, as well as peroxisome proliferator-activated receptor-γ signaling pathways (249–252). The cutoff for a low dose has been set at several different concentrations depending on which studies and definitions are used (see Table 1). The EPA calculated a reference dose for BPA of 50 μg/kg · d based on a LOAEL of 50 mg/kg · d (38). More recent pharmacokinetic scaling experiments have estimated that exposures to approximately 400 μg/kg · d produce blood concentrations of unconjugated BPA in the range of human blood concentrations (4). Thus, for the two WoE analyses of the BPA literature we conducted, doses of 400 μg/kg · d or lower were considered low dose; pharmacokinetic studies from nonhuman primates support the appropriateness of this dose for approximating human exposure levels (253). Furthermore, because this dose is below the toxicological LOAEL, it is a conservative cutoff for low-dose studies (see Refs. 3 and 38 and Table 1).

One of the most well studied and hotly debated examples of a low-dose effect comes from the BPA literature; regulatory agencies and scientists have addressed several times whether low doses of BPA during fetal and perinatal development affect the rodent prostate (118, 205, 254, 255). In 1997, the first study on BPA and the prostate determined that fetal exposure to low doses (2 and 20 μg/kg · d administered orally to pregnant mice) increased the weight of the adult prostate compared with unexposed male offspring (256). Since that time, several additional studies have verified that prostate weight is affected by fetal exposure to similar low doses (257–259). Studies have also shown that low doses of BPA affect androgen receptor binding activity in the prostate (257), tissue organization, and cytokeratin expression in the gland (260–262) as well as the volume of the prostate and the number and size of dorsolateral prostate ducts (208). Several recent studies have also examined whether low doses of BPA (10 μg/kg · d) influence the incidence of adult-onset prostatic intraepithelial neoplasia (PIN) lesions. Perinatal BPA exposure, whether administered orally or sc to pups, increases the incidence of PIN lesions in response to a mixture of testosterone and estradiol in adulthood (139, 141, 263); this hormonal cocktail was designed to mimic the endocrine changes associated with aging in men that also typically accompany the onset of prostate cancer. In addition to the effects of BPA on PIN lesions, these low doses also produced permanent alterations in the epigenome of exposed males, with prostates displaying completely unmethylated sequences in genes that are hypermethylated in unexposed controls (140, 263). In examining these studies, although the same effects of BPA on the prostate were not observed in all studies, there is an obvious trend demonstrating that low doses of BPA during early development significantly affect several aspects of prostate development.

Since the initial report showing effects of low doses on the prostate, approximately nine studies, including several designed specifically to replicate the original positive study, have shown no effects of low doses on the prostate (264–272); every one of these studies examined the prostate weight, and Ichihara *et al.* (264) also examined the effects of BPA on PIN lesions (without hormonal treatment) and the response of the prostate to a chemical carcinogen. Three of these studies failed to include a positive control of any kind (264, 268, 270); three studies used DES as a positive control but found no effect from exposure to this potent xenoestrogen (265–267) (*i.e.* the positive control failed); another study used 17β-estradiol as a positive control, inappropriately administered orally, and found no effects of this hormone on the prostate (271); and two studies used an estrogenic positive control (ethinyl estradiol) and found effects from its exposure, but only at inappropriately high doses (269, 272). These two studies clearly showed that the positive control dose was too high, because rather than increase the weight of the prostate (as seen after low doses of estrogens in other studies), the positive control decreased the weight of the adult prostate (269, 272).

Although this topic was once considered controversial, using a WoE approach, it is clear that there is strong evidence in support of low-dose effects of BPA on the development of the prostate. The evidence clearly shows that several endpoints, including prostate weight, were affected in similar ways in multiple studies from several different labs at doses below 400 μg/kg · d; most effects were seen at doses below 50 μg/kg · d. Furthermore, PIN lesions were reported after neonatal exposure to 10 μg/kg · d with

Downloaded from https://academic.oup.com/edrv/article-abstract/33/3/378/2354852 by guest on 25 February 2019

hormonal treatment in adulthood. No appropriately conducted studies contest this evidence. Therefore, the WoE analysis demonstrates that low doses of BPA significantly alter development of the rodent prostate. The NTP's review of the BPA literature in 2008 indicated that this agency agrees that there is now significant evidence that low-dose BPA adversely affects development of the prostate (273).

D. BPA and the mammary gland: undisputed evidence for low-dose effects

The mammary gland is a conspicuous choice to examine the effects of estrogenic compounds because this organ depends on estrogen for proper development at several critical periods in life (274). The fetal gland expresses ER in the mesenchymal compartment, and just before birth, the epithelium becomes ER positive as well (275). At puberty, estrogen is responsible for ductal elongation and overall development of the gland, allowing the epithelium to fill the stromal compartment in preparation for pregnancy and lactation. Although BPA is an example of a chemical that has been classified as a weak estrogen because it binds with a much lower affinity to ERα compared with 17β-estradiol, even weak estrogens are known to affect the development of the mammary gland during early development (276).

In the first study to examine the effects of BPA on the mammary gland, prepubertal rats were exposed to relatively high doses (100 μg/kg · d or 54 mg/kg · d) for 11 d. After even this short exposure, mammary gland architecture was affected in both dose groups, with increased numbers of epithelial structures and, in particular, structures that suggest advanced development (277). BPA exposure also altered proliferation rates of mammary epithelium and cell cycle kinetics, with an increased number of cells in S-phase and a decreased number of cells in G1. Although relatively high doses of BPA were examined, this initial study indicated that the prepubertal and pubertal gland could be sensitive to BPA.

Many additional studies have examined another critical period, the fetal and neonatal periods, which are sensitive to environmental estrogens (78, 276, 278). Mice exposed prenatally to low doses of BPA via maternal treatment (0.25 μg/kg · d) displayed altered development of both the stromal and epithelial compartments at embryonic d 18, suggesting that exposures affect tissue organization during the period of exposure (176). In addition, similar low doses produced alterations in tissue organization observed in puberty and throughout adulthood, long after exposures ended, and even induced pregnancy-like phenotypes in virgin females (137, 279–282). Female mice exposed to BPA *in utero* displayed heightened responses to estradiol at puberty, with altered morphology of their glands compared with animals exposed to vehicle *in utero* (138). Another study demonstrated that perinatal BPA exposure altered the mammary gland's response to progesterone (283). Remarkably, all of these effects were observed after maternal exposures to low doses (0.025–250 μg/kg), suggesting that the gland is extremely sensitive to xenoestrogen exposures. These studies are in contrast to one that examined the effects of higher doses (0.5 and 10 mg/kg · d) when BPA was administered for 4 d to the dam, which reported advanced development of BPA-exposed glands before puberty but no effects in adulthood (284).

Adult exposure to BPA is only now being examined in the mouse mammary gland model. A recent study examined the effects of BPA on mice with mutations in the *BRCA1* gene. This study reported that 4 wks of exposure to a low dose of BPA altered the tissue organization of the mammary gland in ways that are similar to the effects observed after perinatal exposure (285). This study focused on altered development of the gland during exposure; additional studies are needed to determine whether these effects are permanent or whether normal mammary morphology could be achieved by cessation of BPA exposure.

Another obvious endpoint is the effect of BPA exposure on mammary cancer incidence. Several studies indicate that exposure to BPA *in utero* produces preneoplastic (281, 286, 287) and neoplastic lesions (286) in the gland in the absence of any other treatment. Additionally, other studies show that females exposed to BPA during the perinatal period are more sensitive to mammary carcinogens, decreasing tumor latency and increasing tumor incidence (287–290). These studies are also supported by subsequent studies examining gene and protein expression, which show that low-dose BPA specifically up-regulates expression of genes related to immune function, cell proliferation, cytoskeletal function, and estrogen signaling and down-regulates apoptotic genes (282, 288, 289, 291).

Postnatal BPA exposures also influence mammary cancer incidence; animals exposed lactationally to BPA from postnatal d 2 until weaning displayed decreased tumor latency and increased tumor multiplicity after treatment with DMBA [7,12-dimethylbenz(a)anthracene], a carcinogen (292). This study suggested that BPA exposure led to increased cell proliferation and decreased apoptosis in the gland and shifted the period where the gland is most susceptible to mammary carcinogens, a result that has important implications for human breast cancer. Finally, an additional study examined the effects of adult BPA exposure on mammary cancer; this study demonstrated that low doses of BPA accelerate the appearance of mammary tumors in a tumor-prone mouse strain (293). Interestingly,

Downloaded from https://academic.oup.com/edrv/article-abstract/33/3/378/2354852 by guest on 25 February 2019

high doses did not have this effect; thus, this study is also an excellent example of a NMDRC.

Two studies of BPA and the mammary gland seem to contradict this body of literature, but both examined extremely high doses. In the first study, Nikaido *et al.* (294) exposed female mice to 10 mg/kg BPA from postnatal d 15–18. Mammary glands from these animals were examined at 4, 8, and 24 wk of age, and no differences were observed in the exposed animals relative to controls. Although the lack of effects reported in this study could be due to the high dose employed, they could also be related to the relatively short exposure period during the preweaning phase. In the second study, Yin and colleagues (295) examined the effects of BPA during the first few days after birth (0.1 or 10 mg BPA, equivalent to approximately 10 and 1000 mg/kg) on the incidence of mammary tumors after exposure to a mammary carcinogen at puberty. Similar to the study described above, this one also examined the effects of BPA after a relatively short period of exposure (only three injections administered between postnatal d 2 and 6). Although the study showed that BPA affected tissue organization, there was no change in the incidence of tumors in BPA-exposed females. Because both of these studies examined both high doses and relatively short periods of exposure, it is difficult to compare them directly to the studies finding effects of BPA on the mammary gland after longer exposures to lower doses; at the very least, they cannot refute studies suggesting that BPA alters development of this gland.

In summary, the WoE clearly shows that low-dose BPA exposure affects development of the mammary gland, mammary histogenesis, gene and protein expression in the gland, and the development of mammary cancers. In fact, this example of low-dose effects produced remarkably similar effects across more than a dozen studies conducted in several different labs. These results are also consistent with the effects of low-dose BPA exposure on mammary epithelial cells in culture (reviewed in Ref. 30). Although epidemiology studies examining the influence of BPA on breast cancer rates have proven to be inconclusive at best (296), to replicate the animal studies discussed above, epidemiologists must collect information about prenatal and neonatal exposures and relate them to adult breast cancer incidence. These types of studies would take decades to conduct (67) and should take into consideration the effects of other estrogens, because their effects can be additive or even synergistic (143, 144, 297).

Although our analyses of BPA have focused on its effects on the mammary gland and prostate (see *Sections II.C–D*), it is worth noting that several other endpoints have strong data to support the hypothesis that BPA has low-dose effects. In a recent review using similar WoE approaches, Hunt and colleagues (298) focused on those studies that examined the effects of BPA on the oocyte, specifically scrutinizing studies that reported effects, or no effects, on meiotic aneuploidy and other alterations in the intracellular organization and chromosome abnormalities. Similar to what has been observed with the prostate and mammary gland, the effects observed in the oocyte are variable from study to study, but overall consistent, and suggest that BPA exposure produces defects in these cells.

A large number of studies have also focused on the effects of BPA on the brain and behavior, with the most significant effects on sexually dimorphic regions of the brain and behaviors (299–307). Other affected behaviors include social behaviors, learning and anxiety, and maternal-neonate interactions (reviewed in Refs. 29 and 308). The NTP expert panel statement concluded that there were significant trends in these behavioral data and wrote that there was some concern that BPA could have similar effects in humans (273). Low-dose effects have also been reported for BPA in the female reproductive tract (309, 310), immune system (311, 312), maintenance of body weight and metabolism (313, 314), fertility (315–317), and the male reproductive tract (259, 318) (see Refs. 29 and 319 for comprehensive reviews).

E. Another controversial low-dose example: atrazine and amphibian sexual development

Atrazine is an herbicide that is applied in large volumes to crops, and there is concern that agricultural runoff of this chemical can affect nontarget animal species, especially amphibians that live and reproduce in small ponds and streams where significant amounts of atrazine have been regularly measured (320–322). It is the most commonly detected pesticide in ground and drinking water. Atrazine induces aromatase expression in cells and animals after exposure (323); this ultimately causes an increase in the conversion of testosterone to estrogen (324, 325). This effect has been reported in all vertebrate classes examined: fish, amphibians, reptiles, birds, and mammals, including human cell lines (see Ref. 326 for review). Another well-documented effect of atrazine is that it decreases androgen synthesis and activity, again, in every vertebrate class examined (326). In addition, endocrine-disrupting effects of atrazine occur through a number of other mechanisms, including antiestrogenic activity (327), altered prolactin release (328), and increased glucocorticoid release from the adrenal glands (329, 330), among others (327).

Because of atrazine's indirect effect on estrogen levels, one relevant endpoint that has been given attention is the effect of this chemical on gonad differentiation in various amphibian species. The early gonad is bipotential, and in

Downloaded from https://academic.oup.com/edrv/article-abstract/33/3/378/2354852 by guest on 25 February 2019

mammals, the expression of genes on the Y-chromosome is needed to masculinize the undifferentiated gonad; when this does not occur, the gonad develops into ovarian tissue. In *Xenopus laevis* frogs (and some other animals like birds), the opposite is true: females are heterogametic (*i.e.* ZW-chromosomes) and males have two of the same chromosomes (*i.e.* ZZ). In *X. laevis*, the W-chromosome is the dominant one, containing a gene, DM-W, which induces aromatase expression (331). Thus, having a W-chromosome is needed to produce estrogen; without the conversion of testosterone to estrogen, the frog develops as a male (332). Changes in sex ratio and gonadal morphology are therefore good indicators that an estrogen, or a chemical that up-regulates aromatase and indirectly increases estrogen levels, is present (76).

Determining a low-dose cutoff for atrazine is not a simple task. Although the safe limit of 3 μg/liter in drinking water was set by the EPA, actual levels in the environment often exceed this concentration (333), and levels in ponds and streams can reach 100 μg/liter (322) or more. In traditional toxicology studies examining several amphibian species, the LOAEL was set at 1.1 mg/liter, and the no observed effect level (NOEL) was 200 μg/liter (334, 335). Thus, using the definitions of low dose established by the NTP (2), we consider any treatment at or below 200 μg/liter to be a low dose.

In 2002, one of the first published studies to connect atrazine exposures to altered gonadal morphology examined *X. laevis* frogs exposed to 0.01–200 μg/liter throughout larval development (336). All doses from 0.1–200 μg/liter produced gonadal malformations including the presence of multiple gonads and hermaphroditism. Several other reports showed similar effects of low doses on gonadal phenotypes including studies that report the production of hermaphrodites and intersex frogs, males with ovotestes, and males with testicular oocytes (337–343). Additional studies showed that low-dose atrazine exposure (0.1–200 μg/liter in the water) during sexual differentiation caused testicular dysgenesis, testicular resorption, and testicular aplasia in male frogs (343, 344), and others indicated effects on sex ratios (339, 342, 345, 346). Importantly, these effects were not all observed at the same atrazine concentration, and the studies were conducted in several different species, with some reporting effects at low doses but no effects at higher doses (341) and others reporting effects in some but not all species (339). Examining these studies as a whole, there is clearly a pattern of effects that are reproducible from study to study, and they collectively support the hypothesis that atrazine disrupts sex hormone concentrations.

To date, five peer-reviewed studies have reported no effects of atrazine on sex ratios, gonadal morphology, the incidence of testicular abnormalities or testicular oocytes, gonad size, or the incidence of intersex phenotypes (347–351). Little can be ascertained from these negative studies, however, because four did not include any positive control, suggesting that the frogs used in those studies may have been incapable of responding to atrazine or any other hormonal treatment (347–350). Additionally, one of those studies reported testicular oocytes in the control frogs, suggesting either that the negative control population was contaminated with atrazine (or another EDC or hormone), or that an inappropriate strain of *X. laevis* was selected for the experiments (347). Only one study remains that did not find any effects of atrazine; this study used an appropriate positive control (17β-estradiol) and found effects of that hormone on sex ratios and the incidence of intersex gonads (351). An EPA expert panel noted, however, that this study used a strain of *X. laevis* that was obtained from a new, unexamined population of frogs from Chile and suggested that this strain may be insensitive to environmental chemicals. Furthermore, the panel called for additional analysis of the data in this study, including the statistical approaches; they suggested that an independent laboratory should evaluate the histopathological results; and they requested that atrazine metabolites be measured (352). The panel also proposed that these experiments should be repeated with an established *X. laevis* strain. Taking together the results of those studies that found effects of atrazine on sexual differentiation, and this one negative study, the WoE for the case of low-dose atrazine on sexual differentiation is clearly in support of adverse effects of this chemical.

Just as epidemiological studies have found links between EDCs and human diseases, ecological field studies have examined whether exposure to atrazine in natural environments affects the development of wild amphibians (343, 353–358). These studies have many of the same constraints as those observed in epidemiology: a paucity of data on early life exposures (including exposure levels of controls), limitations on the total number of EDCs that can be measured in environmental and biological samples, and a lack of causative relationships that can be established between exposures and effects. For these reasons, studies that found relationships between atrazine exposure (or concentrations in environmental samples) and effects on one or more aspect of sexual differentiation (343, 353–355) are considered weak, but significant, evidence for low-dose effects. The presence of several studies suggesting a relationship between low-dose exposure to atrazine in the wild and altered sexual differentiation indicates a plausible causal relationship. Because the ecological and laboratory data show similar effects of atrazine on go-

Downloaded from https://academic.oup.com/edrv/article-abstract/33/3/378/2354852 by guest on 25 February 2019

nadal development, this strengthens the conclusions of our WoE that low doses of atrazine cause harm to amphibians.

Feminization of males after atrazine exposure is not restricted to amphibians; exposure of zebrafish to low doses increased the ratio of female to male fish and increased expression of aromatase (359). Close to a dozen additional studies also report that environmentally relevant doses of atrazine can up-regulate aromatase, decrease testosterone, and/or increase estrogen levels in a large number of species (reviewed in Ref. 119), suggesting that low-dose effects of atrazine may be more widespread than their effects on the gonads of amphibians. Other studies indicate that low-dose atrazine affects the immune system and stress responses of salamanders (360–362), survivorship patterns of several frog species (363), and thyroid hormone and plasma ion concentrations in salmon (364).

An important factor to consider when examining the effects of atrazine on different animal models is the difficulty in identifying an appropriate low, environmentally relevant dose for all species. Aquatic animals can be housed in water containing levels of atrazine found in wild habitats, yet no toxicokinetic studies are available to determine what administered dose produces the levels of atrazine metabolites, typically in the parts-per-million or ppb range (365, 366), measured in human samples. There are also no blood or urine measurements in exposed rodents to compare with human levels; thus, extrapolations across species are estimates at best.

Keeping this qualification in mind, exposures in the range of 25–100 mg/kg · d during development have been shown to alter mammary gland development (367, 368), estrous cyclicity (369), serum and intratesticular testosterone concentrations (370), timing of puberty in males and prostate weight (371), and immune function (372) in rodents. Lower doses of atrazine metabolites (0.09–8.73 mg/kg · d) altered development of the mammary gland (373), male pubertal timing and prostate development (374). Identifying the range of doses administered to animals that produce the levels of atrazine and its metabolites measured in human blood and urine is an essential research need to pursue low-dose studies in rodents and other mammals.

F. Dioxin and spermatogenesis: low-dose effects from the most potent endocrine disruptor?

Dioxin, or TCDD, is formed as a byproduct of industrial processes as well as during waste incineration. Because TCDD is extremely toxic to some animals, with 1 μg/kg capable of killing 50% of guinea pigs, it has been labeled the most toxic chemical on earth (375). But interestingly, other animals are less sensitive to lethal effects of TCDD, with an LD_{50} of approximately 1000 μg/kg in hamsters, and studies also suggest that humans are not a hypersensitive species for lethality (376). Additionally, there are differences in the half-life of TCDD in different animals; in rodents, the half-life is 2–4 wks, but in humans, the half-life is approximately 10 yrs, and additional factors influence TCDD pharmacokinetics including the exposure level and the amount of body fat present (377–379). In cell cultures, doses as low as 10^{-11} M are toxic, with decreased viability observed even in cells maintained in nonproliferative states (380).

TCDD binds to the aryl hydrocarbon receptor (AhR), and differences in the affinity for the receptor may be responsible for differences in sensitivity between species (381). The K_d (dissociation constant for receptor-ligand binding kinetics) in human samples typically ranges from 3–15 nM, but in samples from rodents, the K_d is less than 1 nM (382). Importantly, there are also nongenomic pathways affected by TCDD that are mediated by AhR that are typically altered within minutes of TCDD exposure and therefore without changes in transcription (383). Yet many studies suggest that important differences exist between species regarding binding affinity of TCDD for AhR and the toxicity of this chemical, but that other adverse effects, including those related to the endocrine-disrupting activities of TCDD, occur at similar doses (or body burdens) across animal species (384, 385). Thus, it is plausible that AhR affinity alone can predict some, but not all, effects of TCDD and related chemicals.

The mechanisms responsible for many of the endocrine-disrupting activities of TCDD are currently not well understood. Knocking out AhR disrupts morphogenesis of several organ systems even in the absence of a ligand like TCDD, suggesting that this receptor plays important roles in early development (386). AhR is translocated to the nucleus after loss of cell-cell contacts and is often localized to the nucleus in embryonic cells, suggesting that it could have ligand-independent effects on development and/or that endogenous ligands could be present during early development (387). When TCDD is present, AhR translocates to the nucleus and dimerizes with ARNT, the aromatic hydrocarbon receptor nuclear translocator (388). Although the (currently unidentified) physiological activators of AhR are likely to induce rapid on/off signaling via AhR, TCDD and related compounds appear to maintain activation of AhR, and the presence of TCDD prevents the normal action of the AhR signaling pathway in the maintenance of homeostasis (389). This induces changes in the expression of genes and promotes the production of toxic metabolites. These effects may be responsible for some of the endocrine-related endpoints affected by TCDD exposure. Additionally, recent studies have shown complex and intricate interactions between the

Downloaded from https://academic.oup.com/edrv/article-abstract/33/3/378/2354852 by guest on 25 February 2019

AhR and ER signaling pathways (390), suggesting that dioxin may also have indirect effects on some ER-mediated endpoints via AhR signaling.

Teratogenic effects of TCDD have been well documented after high-dose (391, 392) and low-dose exposures (393). These studies show that almost every organ and system in the body is affected by this chemical. High doses that did not produce lethality caused severe weight loss, intestinal hemorrhaging, alopecia, chloracne, edemas, and severe liver damage. Sadly, there are now several examples in humans of accidental exposures after the industrial release of TCDD where a number of individuals have been exposed to large doses (389, 394) as well as a few documented intentional poisonings (395). The tolerated daily intake level was set at 1–4 pg/kg · d, although the doses consumed by nursing infants are likely to exceed these levels by a factor of 10 (375). Adult exposures usually result from the consumption of contaminated foods, and because TCDD is lipophilic, it is concentrated in the fat component of breast milk and therefore passed in large quantities from a nursing mother to her infant.

Using classical toxicology methods, the effects of single TCDD doses were examined in adult male rats, specifically focusing on the effects of this chemical on the number of spermatids per testis and the integrity of the testicular germinal epithelium (396). In one of the earliest studies, Chahoud and colleagues (397) determined a LOAEL of 3 μg/kg · d and set the NOAEL at 1 μg/kg · d for effects on the testes. Because there are significant differences in the toxicity of TCDD between animal models, and different endpoints have different identified NOAELs, we have selected the 1 μg/kg · d identified by Chahoud *et al.* as the cutoff for low-dose studies of this compound. This cutoff is based on the NTP's definition of low dose as occurring at doses lower than those tested in traditional toxicology assessments (2). However, it is important to acknowledge that body burdens that mimic those observed in human populations are likely the best indicators of low doses for TCDD (384), and thus we recommend that future studies determine body burdens after administration of TCDD for the specific strain, origin, and species of animal being tested to ensure that truly low doses, relevant to human populations, are being tested.

Several recent epidemiological studies have indicated that relatively high exposures to TCDD during early life (due to industrial release of high amounts of the chemical) can permanently affect semen quality and sperm count in men (398). Yet epidemiology studies also clearly show that the timing of TCDD exposure can vastly influence the effect of this chemical on spermatogenesis; exposures during perinatal life significantly reduced sperm parameters, but exposures during puberty increased sperm counts; exposures in adulthood had no effect on sperm parameters (399). Thus, it is also important for animal studies to focus on exposures during critical periods for development of the male reproductive tract and spermatogenesis in particular.

We are aware of 18 studies that have examined the effects of low doses ($\leq$1 μg/kg · d) of TCDD during perinatal development on male fertility endpoints in adulthood. The endpoints assessed vary, including epididymal sperm counts, ejaculated sperm number, daily sperm production, sperm transit rate, and percent abnormal sperm, and the sensitivity of these endpoints appears to impact the ability to detect low-dose effects in different studies (400, 401) (Table 5). In total, 16 rodent studies examined the effect of low-dose TCDD on epididymal sperm count; 12 showed significant effects on this endpoint (402–413), whereas the other four did not (414–417). Of the five studies that examined ejaculated sperm counts, four studies (404, 405, 408), including one examining rhesus monkeys (418), showed effects of low-dose TCDD, *i.e.* a significant decrease in sperm counts; one study found no effect (417). Daily sperm production was a less-sensitive endpoint, with four studies showing significant decreases after prenatal exposure to low doses (402, 403, 407, 409) and four studies showing no effects (406, 412, 413, 416); sperm transit rate was examined in only two studies, although both showed significant decreases in sperm tranfer rates (403, 410); and finally, three studies determined that low-dose TCDD produced abnormalities in sperm appearance or motility (414, 415, 419), but one study was not able to replicate these findings (417).

When examining the TCDD literature as a whole, the WoE strongly suggests that prenatal exposure to low doses of TCDD affects sperm-related endpoints in adulthood (Table 5). In all, only two studies were unable to detect any effect of TCDD on the sperm endpoints assessed, although both studies found effects of TCDD on other endpoints including the weight of the adult prostate (416) and the timing of puberty (417). No study on TCDD used a positive control, likely due to a paucity of information on the mechanisms of dioxin action, but this raises obvious questions about the ability of these experimental systems to detect effects on spermatogenesis. Finally, some of the inability to detect effects of TCDD could be due to the use of insensitive strains, because 1000-fold differences in sensitivity have been reported for different rodent strains (420).

Even though we have focused the majority of our attention on the effects of low-dose TCDD exposure on spermatogenesis, it should be noted that low doses of this chemical affect a multitude of endpoints in animals, altering immune function (421, 422), indicators of oxidative

Not significant indicates trend for effect but did not reach statistical significance. Unaffected means assessed, but no differences were observed relative to controls. Here, low doses were considered any at or below 1 μg/kg · d (see text for discussion of how this cutoff was established for rodent studies). NA, Not assessed.

stress (423–425), bone and tooth development (426, 427), female reproduction and timing of puberty (428–430), mammary gland development and suceptibility to cancers (431), behaviors (432, 433), and others. In several cases, lower doses were more effective at altering these endpoints than higher ones (423, 424, 426, 433). Epidemiology studies of nonoccupationally exposed individuals also indicate that serum TCDD levels may be linked to diseases in humans as well (434). Mean serum TCDD levels have decreased by a factor of 7 over a 25-yr period (1972–97) in several industrial nations (435), but results from both animal and epidemiological studies suggest that even the low levels detected now could have adverse effects on health-related endpoints.

G. Perchlorate and thyroid: low-dose effects in humans?

A significant challenge with observing low-dose effects of EDCs in the human population is that human chemical exposures are multivariate along the vectors of time, space, and sensitivities. In addition, chemicals can exert effects on several systems simultaneously. Therefore, associations in human studies between exposures and disease are difficult to reconcile with experimental studies in animal model systems. For this reason, the literature describing the potential impacts of perchlorate contamination on the human population is potentially clarifying because to the best of our knowledge, perchlorate exerts only a single effect, and the pharmacology of perchlorate exposures has been studied in human volunteers (436). This

Downloaded from https://academic.oup.com/edrv/article-abstract/33/3/378/2354852 by guest on 25 February 2019

literature offers a unique perspective into the issue of low-dose effects, perhaps providing important hypotheses to explain mechanistically why high-dose, short-term experiments can fail to predict the outcome of low-dose, lifetime exposures.

In the 2001–2002 NHANES dataset, perchlorate was detected in the urine of each of the 2820 samples tested (437). This widespread exposure means that the human population is being continuously exposed because perchlorate has a half-life in the human body of about 8 h (438). Human exposures to perchlorate are likely attributed to both contaminated drinking water and food (439); in fact, a recent analysis concludes that the majority of human exposure to perchlorate comes from food (440).

The predominant theory proposed to explain the source of perchlorate contamination in the United States is that it has been employed for many decades as the principal oxidant in explosives and solid rocket fuels (441). Perchlorate is chemically stable when wet and persists for long periods in geological systems and in ground water. Because of disposal practices during the 1960s through 1990s, perchlorate became a common contaminant of ground water in the United States (441, 442). Perchlorate is also formed under certain kinds of natural conditions (443), although the relative contributions to human exposure of these different sources is not completely understood. As a result of perchlorate contamination of natural waters, the food supply has become contaminated through irrigation in part because both aquatic and terrestrial plants can concentrate perchlorate more than 100-fold over water levels (444).

This exposure profile in the human population is important because high doses of perchlorate are known to reduce functioning of the thyroid gland, and poor thyroid function is an important cause of developmental deficits and adult disease (445). The primary question is: at what dose does perchlorate inhibit thyroid function sufficiently to cause disease? The current literature, reviewed below, supports the view that background exposure may affect thyroid function in adult women. These exposure levels, however, are considerably lower than predicted by early toxicology experiments in humans.

Perchlorate reduces thyroid function by inhibiting iodide uptake by the sodium/iodide symporter (NIS) (446), which is the only known effect of perchlorate on human physiology (438). NIS is responsible for transporting iodide into the thyroid gland, which is required for the production of thyroid hormone (447). However, NIS is also expressed in the gut (448, 449), in lactating breast (448, 450, 451), and in placenta (452), presumably all as a delivery mechanism for iodide to the developing and adult thyroid gland. Because the NIS transports perchlorate (450), the pathway by which humans take up and concentrate perchlorate is the same as the pathway by which humans take up and concentrate iodide. Interestingly, NIS expression in the human fetal thyroid gland is the rate-limiting step in production of thyroid hormone (453). Moreover, NIS transport of perchlorate explains why high levels of perchlorate are found in human amniotic fluid (454, 455) and breast milk (456–459).

This effect of perchlorate on thyroid function is important because thyroid hormone is essential for normal brain development, body growth as well as for adult physiology (445, 460). Moreover, it has become clear that even small deficits in circulating thyroid hormone in pregnant women (461, 462) or neonates (463) have permanent adverse outcomes. In fact, recent work indicates that very subtle thyroid hormone insufficiency in pregnant women is associated with cognitive deficits in their children (461). Because of the importance of thyroid hormone in development and adult physiology, and because perchlorate is a potent inhibitor of iodide uptake and thyroid hormone synthesis, identifying the dose at which these events occur is critical.

Perchlorate was used medically to reduce circulating levels of thyroid hormone in patients with an overactive thyroid gland in the 1950s and 1960s (reviewed in Ref. 446); therefore, it was reasonable to examine the dose-response characteristics of perchlorate on the human thyroid gland. Because perchlorate inhibits iodide uptake, several studies were performed to evaluate the effect of perchlorate exposure on iodide uptake inhibition in human volunteers (438, 464–466). In one study, 0.5 or 3 mg/d (approximately 0.007 and 0.04 mg/kg · d) perchlorate was administered to healthy volunteers (n = 9 females and 5 males, age 25–65 yr), and no effects were observed (466). Of course, it is important to note that the 2 wk of administration tested in this study is not sufficient to see any effect on serum concentrations of T_4 or TSH; the healthy thyroid can store several months' worth of thyroid hormone in the gland (467). Another small study also found no effects of administering 3 mg/d (approximately 0.04 mg/kg · d) on any thyroid endpoint assessed (n = 8 adult males) (464).

In contrast, two studies examining adult volunteers administered perchlorate found effects of this chemical on at least one endpoint. The first found that radioactive iodide uptake was affected by 2 wk of exposure to 10 mg/d (0.13 mg/kg · d), but other measures of thyroid function were not altered (n = 10 males) (465). The second examined adults (n = 37) given doses ranging from 0.007–0.5 mg/kg · d; all but the lowest dose altered radioactive iodide uptake, and only the highest dose altered TSH levels (438). These studies were interpreted to suggest that adults would have to consume 2 liters of drinking water daily that

Downloaded from https://academic.oup.com/edrv/article-abstract/33/3/378/2354852 by guest on 25 February 2019

was contaminated with at least 200 ppb (200 μg/liter) perchlorate to reach a level in which iodide uptake would begin to be inhibited. Yet, these administered doses are high and relatively acute, so the derivation of a safe dose from these studies, applied to vulnerable populations such as those with low iodide intake, has been strongly disputed (471).

Studies of occupational exposures have also been used to examine the effects of exposure to relatively high levels of perchlorate. In the first such study, more than 130 employees were separated into eight groups based on exposure estimates from airborne perchlorate in the workplace (472). The authors found that individuals with longer daily exposures to perchlorate, due to longer work shifts, had significant decreases in TSH levels compared with individuals with shorter exposures. But this study was hampered because actual exposure levels were not measured via urine or blood samples. A second study examined 37 employees exposed to perchlorate and 21 control employees from an azide factory; actual exposure measures were not conducted, but estimates were calculated based on exposures to perchlorate dust and air samples (473). This study found no effects of perchlorate exposures on any thyroid endpoint, although the sample size examined was small. In the final occupational exposure study, serum perchlorate levels were measured and compared with several measures of thyroid function in workers (n = 29) who had spent several years as employees in a perchlorate production plant (474). In this study, the most complete because of the biomonitoring aspect of the exposure measures, higher perchlorate levels were associated with lower radioactive iodide uptake, higher urinary iodide excretion, and higher thyroid hormone concentrations.

Although iodide uptake was often inhibited in these studies, serum thyroid hormones were typically not altered, perhaps because of sufficient stored hormone. Based on these observations, the National Academy Committee to Assess the Health Implications of Perchlorate Ingestion (467) estimated that perchlorate would have to inhibit thyroid iodide uptake by about 75% for several months to cause a reduction in serum thyroid hormones. Moreover, the drinking water concentration of perchlorate required for this kind of inhibition was estimated to be over 1,000 ppb (438). Therefore, the National Academy of Sciences committee recommended a reference dose of 0.0007 mg/kg · d (467), based on the dose at which perchlorate could inhibit iodide uptake, and the EPA used this value to set a provisional drinking water standard of 15 ppb.

Considering these data and general knowledge about the thyroid system, it was unexpected that Blount *et al.* (475) would identify a positive association between urinary iodide and serum TSH in adult women in the NHANES 2001–2002 dataset. Yet several features of this dataset were consistent with a causal action of perchlorate on thyroid function. First, in the general population of adult women, urinary perchlorate was positively associated with serum TSH. In the population of adult women who also had low urinary iodide, however, urinary perchlorate was more strongly associated with serum TSH and was negatively associated with serum T_4. The strength of this association was such that the authors calculated that women at the 50th percentile of perchlorate exposure experienced a 1 μg/dl T_4 reduction (reference range = 5–12 μg/dl). Should this magnitude of reduction in serum T_4 occur in a neonate, measurable cognitive deficits would also be present (476). Finally, Steinmaus *et al.* (477), using the same NHANES dataset, showed that women with low urinary iodide who smoke had an even stronger association between urinary perchlorate and measures of thyroid function. Tobacco smoke delivers thiocyanates, which also inhibit NIS-mediated iodide uptake (446).

The NHANES dataset suggests that perchlorate exposures of 0.2–0.4 μg/kg · d (440) are associated with depressed thyroid function, even when urinary iodide is not reduced. This is a considerably lower dose than the 7 μg/kg · d dose required to suppress iodide uptake in the Greer *et al.* (438) study or the 500 μg/kg · d the NAS estimated would be required for several months to actually cause a decline in serum T_4. Therefore, it is reasonable to question whether these associations represent a causative relationship between perchlorate and thyroid function.

A number of epidemiological studies have been published to test for a relationship between perchlorate exposure and thyroid function. Early work used neonatal screening data for T_4 as a measure of thyroid function, and the city of birth (Las Vegas, NV, compared with Reno, NV) as a proxy measure of exposure (478, 479). The reported findings were negative, but we now know that all Americans are exposed to perchlorate, so there was considerable misclassification of exposure, and no relationship should have been observed. Several additional studies using similar flawed designs also found no relationship between proxy measures of perchlorate exposures and clinical outcomes (480–484).

A recent study of the neonatal screening data from 1998 in California identified a strong association between neonatal TSH and whether or not the mother resided in a contaminated area (485). This study included over 497,000 TSH measurements and 800 perchlorate measurements. In addition, they used as a cutoff a variety of TSH levels (as opposed to the 99.9th percentile used for the diagnosis of congenital hypothy-

Downloaded from https://academic.oup.com/edrv/article-abstract/33/3/378/2354852 by guest on 25 February 2019

roidism), indicating that perchlorate exposure is not associated with congenital hypothyroidism. Two additional studies have shown similar relationships between perchlorate and TSH levels, particularly in families with a history of thyroid disease (486, 487).

Several studies in pregnant women have failed to identify a relationship between perchlorate exposure and measures of thyroid function (488–490). Although these are important studies that need to be carefully scrutinized, they do not replicate or refute the NHANES dataset. It thus remains important to conduct additional studies exploring the relationship between background exposure to perchlorate and thyroid function in adults, pregnant women, neonates, and infants. This effort will be challenging because of the different characteristics of thyroid function and hormone action at different life stages (460). In addition, it will be important to obtain individual measurements of exposures to perchlorate and other NIS inhibitors (thiocyanate and nitrate), and iodide itself as well as individual measures of thyroid function (free and total T_4 and TSH).

If background levels of perchlorate affect thyroid function in any segment of the population, it will be challenging to explain how the high-dose, short-term experiments of Greer *et al.* (438) completely underestimated the sensitivity of the human thyroid gland to perchlorate exposure. One possibility is that physiological systems respond to short durations of robust stress with compensatory mechanisms that reset during periods of long-term stress.

When these data are examined together, several important issues are raised. First, this example illustrates the difficulties inherent in studying human populations; epidemiology yields associations, not cause-effect relationships, in many cases using surrogate markers for perchlorate, and is not able to distinguish short- *vs.* long-term exposure duration. Second, our WoE analysis suggests that there is weak evidence for low-dose effects of perchlorate; further research is needed. The relationship between low-dose perchlorate exposures and thyroid endpoints would be strengthened by the addition of studies that measure biological concentrations of perchlorate and compare them with thyroid endpoints in neonates and other vulnerable populations. Third, the published studies that reported low-dose effects of perchlorate typically examined very specific populations, with several focusing on women with low iodine intake. This observation suggests that some groups may be more vulnerable to low doses of perchlorate than others (491).

H. Low-dose summary

These examples, and the examples of low-dose effects in less well-studied chemicals (Table 3), provide evidence that low-dose effects are common in EDC research and may be the default expectation for all chemicals with endocrine activity. Many known EDCs have not been examined for low-dose effects, but we predict that these chemicals will have effects at low doses if studied appropriately. Although studies unable to detect effects at low doses have received attention, including some studies designed to replicate others that reported low-dose effects, the majority of these studies contain at least one major design flaw. Thus, a WoE approach clearly indicates that low-dose effects are present across a wide span of chemical classes and activities.

III. Nonmonotonicity in EDC Studies

A concept related to low dose is that of nonmonotonicity. As noted in *Section I.B*, in a monotonic response, the observed effects may be linear or nonlinear, but the slope does not change sign (Fig. 3, A and B). In contrast, a dose-response curve is nonmonotonic when the slope of the curve changes sign somewhere within the range of doses examined (Fig. 3C). NMDRCs are often U-shaped (with maximal responses of the measured endpoint observed at low and high doses) or inverted U-shaped (with maximal responses observed at intermediate doses) (Fig. 3C, *top panels*). Some cases are more complicated, with multiple points along the curve at which the slope of the curve reverses sign (Fig. 3C, *bottom left*). Nonmonotonicity is not synomymous with low dose, because there are low-dose effects that follow monotonic dose-response curves. Thus, it is not required that a study include doses that span from the true low-dose range to the high toxicological range to detect nonmonotonicity. The consequence of NMDRCs for toxicity testing is that a safe dose determined from high doses does not guarantee safety at lower, untested doses that may be closer to current human exposures.

Examples of NMDRCs from the cell culture, animal, and epidemiological literature will be discussed in detail in *Section III.C*. Importantly, our review of the literature finds that NMDRCs are common in the endocrine and EDC literature. In fact, it is plausible that, considering the mechanisms discussed below, NMDRCs are not the exception but should be expected and perhaps even common.

A. Why is nonmonotonicity important?

NMDRCs in toxicology and in the regulatory process for EDCs are considered controversial. In addition to discussions of whether NMDRCs exist, there is also discussion of whether those that do exist have relevance to

Downloaded from https://academic.oup.com/edrv/article-abstract/33/3/378/2354852 by guest on 25 February 2019

Figure 3.

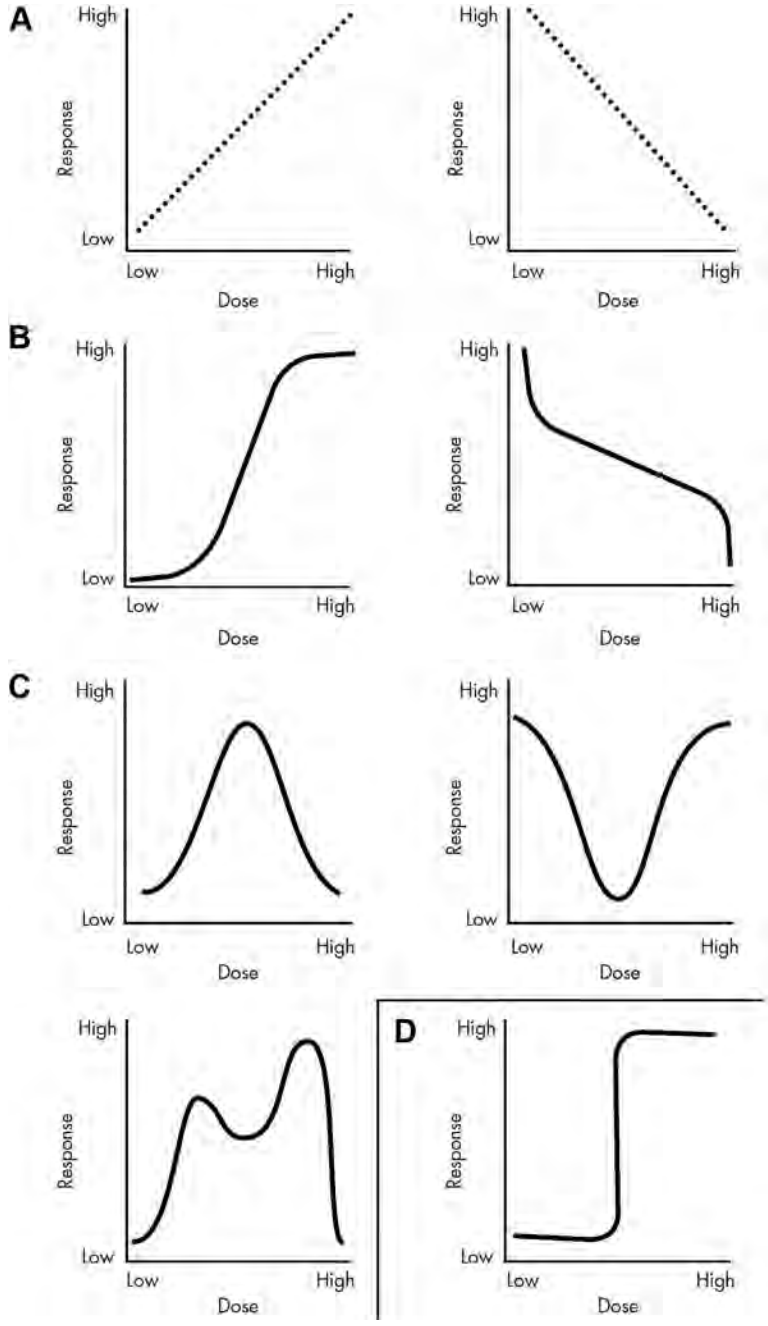

Figure 3. Examples of dose-response curves. A, Linear responses, whether there are positive or inverse associations between dose and effect, allow for extrapolations from one dose to another. Therefore, knowing the effects of a high dose permits accurate predictions of the effects at low doses. B, Examples of monotonic, nonlinear responses. In these examples, the slope of the curve never changes sign, but it does change in value. Thus, knowing what happens at very high or very low doses is not helpful to predict the effect of exposures at moderate doses. These types of responses often have a linear component within them, and predictions can be made within the linear range, as with other linear responses. C, Displayed are three different types of NMDRCs including an inverted U-shaped curve, a U-shaped curve, and a multiphasic curve. All of these are considered NMDRCs because the slope of the curve changes sign one or more times. It is clear from these curves that knowing the effect of a dose, or multiple doses, does not allow for assumptions to be made about the effects of other doses. D, A binary response is shown, where one range of doses has no effect, and then a threshold is met, and all higher doses have the same effect.

toxicological determination of putative safe exposures. In the standard practice of regulatory toxicology, the calculated safe dose, also called a reference dose, is rarely tested. In a system that is responding nonmonotonically, it is not appropriate to use a high-dose test to predict low-dose effects. Unfortunately, all regulatory testing for the effects of chemical exposures assume that this is possible. All current exposure standards employed by government agencies around the world, including the FDA and EPA, have been developed using an assumption of monotonicity (492, 493). The low-dose range, which presumably is what the general public normally experiences, is rarely, if ever, tested directly.

The standard procedure for regulatory testing typically involves a series of tests to establish the lowest dose at which an effect is observable (the LOAEL), then a dose beneath that at which no effect is observable (the NOAEL). Then a series of calculations are used to acknowledge uncertainty in the data, species differences, age differences, *etc.*, and those calculations, beginning with the LOAEL or the NOAEL, produce a reference dose that is presumed to be a safe exposure for humans (Fig. 4). Typically, the reference dose is 3- to 1000-fold lower than the NOAEL. That reference dose then becomes the allowable exposure and is deemed safe, even when it is never examined directly. For chemicals with monotonic linear dose-response curves (Fig. 3A), this may be appropriate. But for chemicals that display nonmonotonic patterns, it is likely to lead to false negatives, *i.e.* concluding that exposure to the reference dose is safe when in fact it is not.

As described above, there are other nonlinear dose-response curves that are monotonic (Fig. 3B). These curves may also present problems for extrapolating from high doses to low doses because there is no linear relationship that can be used to predict the effects of low doses. Equally troubling for regulatory purposes are responses that have a binary response rather than a classical dose-response curve (Fig. 3D). In these types of responses, one range of doses has no effect on an endpoint, and then a threshold is met, and all higher doses have the same effect. An example is seen in the atrazine literature, where doses below 1 ppb had no effect on the size of the male larynx but doses

Downloaded from https://academic.oup.com/edrv/article-abstract/33/3/378/2354852 by guest on 25 February 2019

at or above 1 ppb produced a significant decrease in size of approximately 10–15% (336). Even doses of 200 ppb, the toxicological NOEL, produce the same effect. Thus, this all-or-none effect is observed because atrazine does not shrink the larynx; instead, it removes the stimulatory agent (*i.e.* androgens). In the absence of some threshold dose of androgen, the larynx simply remains at the unstimulated (female) size. The EPA's assessment of this study and others was that the lack of a dose-dependent response negates the importance of this effect (352). The lack of a dose response for a threshold effect like larynx size does not mean that the effects are not dose dependent; thus, understanding these types of effects and their implications for risk assessments is essential for determining the safe levels of chemicals.

It is important to mention here that the appropriateness of determining NOAEL concentrations, and therefore calculating reference doses, from exposures to endogenous hormones or EDCs has been challenged by several studies (Fig. 4A) (494–496). These studies show that hormonally active agents may still induce significant biological effects even at extremely low concentrations and that presently available analytical methods or technologies might be unable to detect relatively small magnitudes of effects. Previous discussions of this topic have shown that as the dose gets lower (and approaches zero) and the effect size decreases, the number of animals needed to achieve the power to detect a significant effect would have to increase substantially (497). Even more importantly, the assumption of a threshold does not take into account situations where an endogenous hormone is already above the dose that causes detectable effects and that an exogenous chemical (whether an agonist or antagonist) will modulate the effect of the endogenous hormone at any dose above zero (Fig. 4B). There can thus be no threshold or safe dose for an exogenous chemical in this situation. Forced identification of NOAEL or threshold doses based on the assumption that dose-response curves are always monotonic without considering the background activity of endogenous hormones and the limitations of analytical techniques supports the misconception that hormonally active agents do not have any significant biological effects at low doses. Thus, the concept that a toxic agent has a safe dose that can be readily estimated from the NOAEL derived from testing high, acutely toxic doses is overly simplistic and contradicted by data when applied to EDC (5, 497, 498).

B. Mechanisms for NMDRCs

Previously, the lack of mechanisms to explain the appearance of NMDRCs was used as a rationale for ignoring these phenomena (492, 493). This is no longer acceptable because there are several mechanisms that have been identified and studied that demonstrate how hormones and EDCs produce nonmonotonic responses in cells, tissues, and animals. These mechanisms include cytotoxicity, cell- and tissue-specific receptors and cofactors, receptor selectivity, receptor down-regulation and desensitization, receptor competition, and endocrine negative feedback loops. These mechanisms are well understood, and by providing detailed biological insights at the molecular level into the etiology of NMDRCs, they strongly negate the presumption that has been central to regulatory toxicology that dose-response curves are by default monotonic.

1. Cytotoxicity

The simplest mechanism for NMDRCs derives from the observation that hormones can be acutely toxic at high doses yet alter biological endpoints at low, physiologically relevant doses. Experiments working at concentrations that are cytotoxic are incapable of detecting responses that are mediated by ligand-binding interactions. For example, the MCF7 breast cancer cell line proliferates in response to estradiol in the low-dose range (10^{-12} to 10^{-11} M) and in the pharmacological and toxicological range (10^{-11} to 10^{-6} M), but toxic responses are observed at higher doses (38). Thus, when total cell number is graphed, it displays an inverted U-shaped response to estrogen. But cells that do not contain ER, and therefore cannot be affected by the hormonal action of estradiol, also display cytotoxic responses when treated with high doses of hormone. These results clearly indicate that the effects of estradiol at high doses are toxic via non-ER-mediated mechanisms.

2. Cell- and tissue-specific receptors and cofactors

Some NMDRCs are generated by the combination of two or more monotonic responses that overlap, affecting a common endpoint in opposite ways via different pathways. For example, *in vitro* cultured prostate cell lines demonstrate a nonmonotonic response to increasing doses of androgen where low doses increase cell number and higher doses decrease cell number, thus producing an inverted U-shaped curve (499, 500). Although the parental cell expressed an inverted U-shaped dose-response curve, after a long period of inhibition, the effects on cell number could be segregated by selecting two populations of cells: one that proliferated in the absence of androgens and other cells that proliferated in the presence of high androgen levels (501). Thus, the observed inverted U-shaped response is due to actions via two independent pathways that can be separated from each other in an experimental setting (502). Similarly, estrogens have been shown to induce cell proliferation and inhibit apoptosis in several cell populations, but inhibit proliferation and induce apopto-

Figure 4.

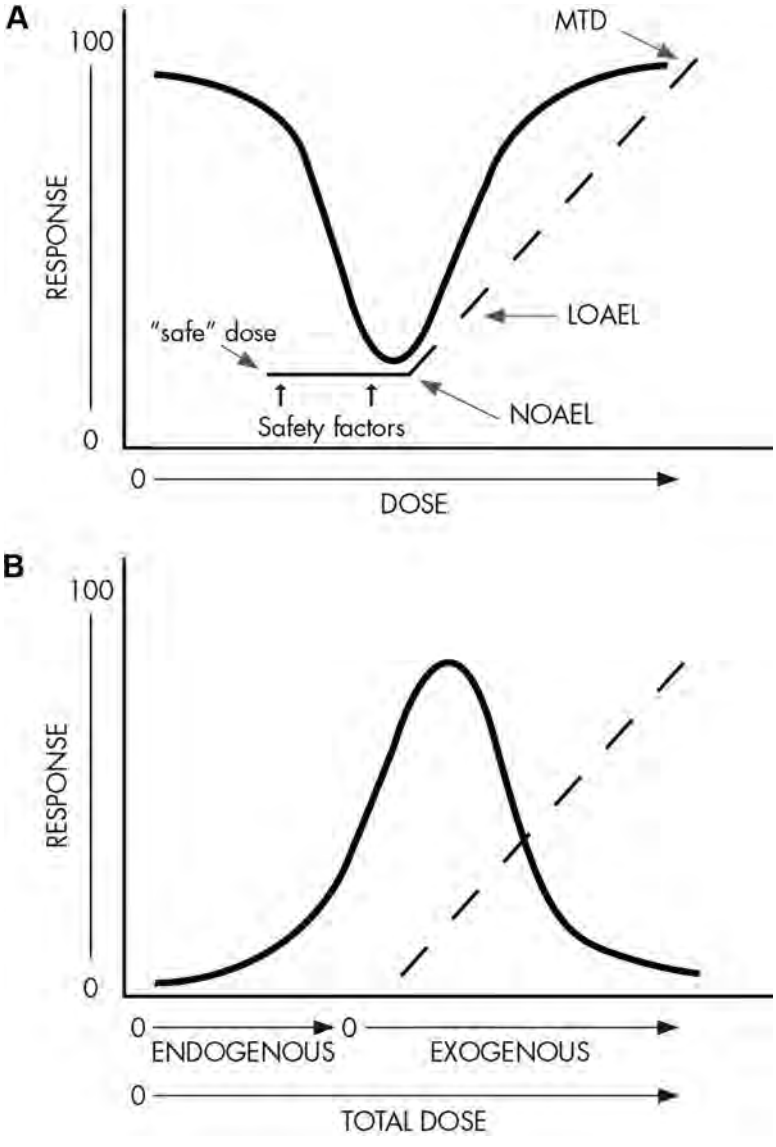

Figure 4. NOAEL, LOAEL, and calculation of a safe reference dose. A, In traditional toxicology testing, high doses are tested to obtain the maximum tolerated dose (MTD), the LOAEL, and the NOAEL. Several safety factors are then applied to derive the reference dose, *i.e.* the dose at which exposures are presumed safe. This reference dose is rarely tested directly. Yet when chemicals or hormones produce NMDRCs, adverse effects may be observed at or below the reference dose. Here, the doses that would be tested are shown by a *dotted line*, and the calculated safe dose is indicated by a *thick solid line*. The actual response, an inverted U-shaped NMDRC, is shown by a *thin solid line*. B, Experimental data indicate that EDCs and hormones do not have NOAELs or threshold doses, and therefore no dose can ever be considered safe. This is because an exogenous hormone (or EDC) could have a linear response in the tested range (*dotted line*), but because endogenous hormones are present (*thin solid line*), the effects of the exogenous hormone are always observed in the context of a hormone-containing system.

sis in others (503, 504), with the combined effect being an inverted U-shaped curve for cell number (505).

Why does one single cell type have different responses to different doses of the same hormone? The case of the prostate cell line described above is reminiscent of the results described from the transcriptome of MCF7 cells, whereby a discrete global response like cell proliferation manifests at significantly lower estrogen doses than the induction of a single marker gene (135). That a response like cell proliferation requires a significantly lower dose of hormone than the dose needed to induce a given target gene is counterintuitive but factual; it may be interpreted as consistent with the notion that metazoan cells, like cells in unicellular organisms, are intrinsically poised to divide (503, 506, 507) and that quiescence is an induced state (508, 509). The biochemical details underlying these different responses are largely unknown; however, recent studies showed that steroid receptors control only a portion of their target genes directly via promoter binding. The majority of the changes are indirect, through chromatin rearrangements (510, 511).

Why do different cell types (*in vitro* and *in vivo*) have different responses to the same hormone? One answer is that they may express different receptors, and these receptors have different responses to the same hormone. For example, some tissues express only one of the two major ER (ERα and ERβ), and actions via these receptors are important not just for responsiveness to hormone but also for cellular differentiation and cross talk between tissue compartments (512). Yet other tissues express both ERα and ERβ, and the effects of signaling via these two receptors often oppose each other; *i.e.* estrogen action via ERα induces proliferation in the uterus, but ERβ induces apoptosis (154). Complicating the situation further, different responses to a hormone can also be obtained due to the presence of different cofactors in different cell and tissue types (513, 514); these coregulators influence which genes are transcriptionally activated or repressed in response to the presence of hormone. They can also influence ligand selectivity of the receptor and DNA-binding capacity, having tremendous impact on the ability of a hormone to have effects in different cell types (105, 515, 516).

Although much of these activities occur on a biochemical level, *i.e.* at the receptor, there is also evidence that nonmonotonicity can originate at the level of tissue organization. The mammary gland has been used as a model to study inter- and intracompartmental effects of hormone treatment: within the ductal epithelium, estro-

Downloaded from https://academic.oup.com/edrv/article-abstract/33/3/378/2354852 by guest on 25 February 2019

gen has distinct effects during puberty, both inducing proliferation, which causes growth of the ductal tree, and inducing apoptosis, which is required for lumen formation (517, 518); in cell culture, the presence of stromal cells can also enhance the effects of estrogen on epithelial cells (519, 520), suggesting that stromal-epithelial compartmental interactions can mediate the effects of estrogen.

3. Receptor selectivity

NMDRCs can occur because of differences in receptor affinity, and thus the selectivity of the response, at low *vs.* high doses. For example, at low doses, BPA almost exclusively binds to the ER (including mER), but at high doses it can also bind weakly to other hormone receptors, like androgen receptor and thyroid hormone receptor (249, 521). This type of receptor nonselectivity is quite common for EDCs, and it has been proposed that binding to different receptors may be an explanation for the diverse patterns of disease observed after EDC exposures (522). In fact, several of the chemicals shown to have low-dose effects are known to act via multiple receptors and pathways (Table 3). Thus, the effects seen at high doses can be due to action via the binding of multiple receptors, compared with the effects of low doses, which may be caused by action via only a single receptor or receptor family.

4. Receptor down-regulation and desensitization

When hormones bind to nuclear receptors, the ultimate outcome is a change in the transcription of target genes. When the receptor is bound by ligand, an increase in response is observed; as discussed previously in this review, the relationship between hormone concentration and the number of bound receptors, as well as the relationship between the number of bound receptors and the biological effect, is nonlinear (38). After the nuclear receptor is bound by hormone and transcription of target genes has occurred (either due to binding of the receptor at a DNA response element or the relief of a repressive event on the DNA), the reaction eventually must cease; *i.e.* the bound receptor must eventually be inactivated in some way. Thus, nuclear hormone receptors are ubiquitinated and degraded, usually via the proteasome (523). Importantly, the role of the hormone in receptor degradation differs depending on the hormone; binding of estrogen, progesterone, and glucocorticoid mediates the degradation of their receptors (524–526), whereas the presence of hormone may actually stabilize some receptors and prevent degradation (527), and other receptors are degraded without ligand (528). As hormone levels rise, the number of receptors being inactivated and degraded also rises, and eventually the number of receptors being produced cannot maintain the pace of this degradation pathway (523). Furthermore, the internalization and degradation of receptors can also influence receptor production, leading to an even stronger down-regulation of receptor (529). In the animal, the role of receptor down-regulation is actually quite complex, because signaling from one hormone receptor can influence protein levels of another receptor; *i.e.* ER signaling can promote degradation of the glucocorticoid receptor by increasing the expression of enzymes in the proteasome pathway that degrade it (530).

There is also the issue of receptor desensitization, a process whereby a decrease in response to a hormone is not due to a decrease in the number of available receptors but instead due to the biochemical inactivation of a receptor (531). Desensitization typically occurs when repeated or continuous exposure to ligand occurs. Normally seen with membrane-bound G protein-coupled receptors, the activation of a receptor due to ligand binding is quickly followed by the uncoupling of the activated receptor from its G proteins due to phosphorylation of these binding partners (532). Receptor desensitization has been observed for a range of hormones including glucagon, FSH, human chorionic gonadotropin, and prostaglandins (533). Importantly, desensitization and down-regulation can occur in the same cells for the same receptor (534), and therefore, both can play a role in the production of NMDRCs.

5. Receptor competition

Mathematical modeling studies suggest that the mixture of endogenous hormones and EDCs establishes a natural environment to foster NMDRCs. Using mathematical models, Kohn and Melnick (42) proposed that when EDC exposures occur in the presence of endogenous hormone and unoccupied hormone receptors, some unoccupied receptors become bound with the EDC, leading to an increase in biological response (*i.e.* increased expression of a responsive gene, increased weight of an organ, *etc.*). At low concentrations, both the endogenous hormone and the EDC bind to receptors and activate this response, but at high doses, the EDC can outcompete the natural ligand. The model predicts that inverted U-shaped curves would occur regardless of the binding affinity of the EDC for the receptor and would be abolished only if the concentration of natural hormone were raised such that all receptors were bound.

6. Endocrine negative feedback loops

In several cases, the control of hormone synthesis is regulated by a series of positive- and negative feedback loops. Several hormones are known to control or influence their own secretion using these feedback systems. In one example, levels of insulin are known to regulate glucose uptake by cells. Blood glucose levels stimulate insulin pro-

Downloaded from https://academic.oup.com/edrv/article-abstract/33/3/378/2354852 by guest on 25 February 2019

duction, and as insulin removes glucose from circulation, insulin levels decline. Thus, NMDRCs can occur as the free/available ligand and receptor concentrations are influenced by one another. In another example, thyroid hormone secretion is stimulated by TSH, and thyroid hormone suppresses TSH; thus, feedback between these two hormones allows thyroid hormone to be maintained in a narrow dose range.

Several studies indicate that these negative feedback loops could produce NMDRCs when the duration of hormone administration is changed (535). For example, short exposures of estrogen induce proliferation in the uterus and pituitary, but longer hormone regimens inhibit cell proliferation (236, 536). Thus, the outcome is one where exposure to a single hormone concentration stimulates an endpoint until negative feedback loops are induced and stimulation ends (537).

7. Other downstream mechanisms

Removing the variability that can come from examining different cell types, or even single cell types in the context of a tissue, studies of cultured cells indicate that different gene profiles are affected by low doses of hormone compared with higher doses. In a study of the genes affected by low *vs.* higher doses of estrogen, researchers found that there were a small number of genes in MCF7 breast cancer cells with very high sensitivity to low doses of estradiol (10 pM) compared with the total number of genes that were affected by higher (30 or 100 pM) exposures (538). But the surprising finding was the pattern of estradiol-induced *vs.* estradiol-suppressed gene expression at high and low doses; when 10 pM was administered, the number of estradiol-suppressible genes was approximately three times higher than the number of estradiol-inducible genes. However, the overall profile of the number of estradiol-suppressible genes was approximately half the total number of estradiol-inducible genes. This observation suggests that low doses of estrogen selectively target a small subset of the total number of estrogen-sensitive genes and that the genes affected by low doses are most likely to be suppressed by that treatment. The mechanisms describing how low doses of estrogen differently affect the expression of genes compared with higher doses have yet to be elucidated, but low doses of estradiol inhibit expression of apoptotic genes (539), indicating that which genes are affected by hormone exposure is relevant to understand how low doses influence cellular activities.

C. Examples of nonmonotonicity

1. Examples of NMDRCs from cell culture

A tremendous amount of theoretical and mathematical modeling has been conducted to understand the production of nonlinear and nonmonotonic responses (42, 540). These studies and others suggest that the total number of theoretical response curves is infinite. Yet this does not mean that the occurrence of NMDRCs is speculative; these types of responses are reported for a wide variety of chemicals. Cell culture experiments alone provide hundreds of examples of nonmonotonic responses (see Table 6 for examples). In the natural hormone category, many different hormones produce NMDRCs; this is clearly not a phenomenon that is solely attributable to estrogen and androgen, the hormones that have been afforded the most attention in the dose-response literature. Instead, NMDRCs are observed after cells are treated with a range of hormones, suggesting that this is a fundamental and general feature of hormones.

Chemicals from a large number of categories with variable effects on the endocrine system also produce NMDRCs in cultured cells. These chemicals range from components of plastics to pesticides to industrial chemicals and even heavy metals. The mechanisms for nonmonotonicity discussed in *Section III.B* are likely explanations for the NMDRCs reported in a range of cell types after exposure to hormones and EDCs. Table 6 provides only a small number of examples from the literature, and it should be noted that because these are studies of cells in culture, most of these studies typically examined only a few types of outcomes: cell number (which could capture the effects of a chemical on cell proliferation, apoptosis, or both), stimulation or release of another hormone, and regulation of target protein function, often examined by measuring the phosphorylation status of a target.

2. Examples of NMDRCs in animal studies

Some scientists suggest that nonmonotonicity is an artifact of cell culture, however, a large number of NMDRCs have been observed in animals after administration of natural hormones and EDCs, refuting the hypothesis that this is a cell-based phenomenon only. Similar to what has been observed in cultured cells, the NMDRCs observed in animals also span a large range of chemicals, model organisms, and affected endpoints (Table 7). These results underscore the biological importance of the mechanisms of nonmonotonicity that have been largely worked out *in vitro*.

Although NMDRCs attributable to estrogen treatment are well documented, the induction of NMDRCs is again observed to be a general feature of hormone treatment; a wide range of hormones produce these types of responses in exposed animals. Importantly, a number of pharmaceutical compounds with hormone-mimicking or endocrine-disrupting activities also produce NMDRCs. Finally, as expected from the results of cell culture

TABLE 6. Examples of NMDRCs in cell culture experiments

Chemicals by chemical class	Nonmonotonic effect	Cell type	Refs.
Natural hormones			
17β-Estradiol	Cell number	MCF7 breast cancer cells	135, 716
	Dopamine uptake	Fetal hypothalamic cells (primary)	717
	pERK levels, prolactin release	GH3/B6/F10 pituitary cells	41, 718, 719
	β-Hexosaminidase release	HMC-1 mast cells	720
	Cell number	Vascular smooth muscle cells	721
	Production of L-PGDS, a sleep-promoting substance	U251 glioma cells	722
5α-Dihydrotestosterone	Cell number	LNCaP-FGC prostate cancer cells	499
	Cell number, kinase activity	Vascular smooth muscle cells	721
5α-Androstenedione	Cell number	LNCaP-FGC prostate cancer cells	499
Corticosterone	Mitochrondrial oxidation, calcium flux	Cortical neurons (primary)	723
Insulin	Markers of apoptosis (in absence of glucose)	Pancreatic β-cells (primary)	724
Progesterone	Cell number	LNCaP-FGC prostate cancer cells	499
Prolactin	Testosterone release	Adult rat testicular cells (primary)	725
hCG	Testosterone release	Adult rat testicular cells (primary)	725
T_3	Rate of protein phosphorylation	Cerebral cortex cells (primary, synaptosomes)	726
	LPL mRNA expression	White adipocytes (rat primary)	727
GH	*IGF-I* expression	Hepatocytes (primary cultures from silver sea bream)	728
Pharmaceutical hormones			
DES	Cell number	MCF7 breast cancer cells	716
	Prolactin release	GH3/B6/F10 pituitary cells	41
Ethinyl estradiol	CXCL12 secretion	MCF7 breast cancer cells, T47D breast cancer cells	729
R1881 (synthetic androgen)	Cell number	LNCaP-FGC cells	499
Trenbolone	Induction of micronuclei	RTL-W1 fish liver cells	730
Plastics			
BPA	Cell number	MCF7 breast cancer cells	135, 716
	Dopamine efflux	PC12 rat tumor cells	40
	pERK levels, intracellular Ca^{2+} changes, prolactin release	GH3/B6/F10 pituitary cells	41, 718
	Cell number	LNCaP prostate cancer cells	731
DEHP	Number of colonies	*Escherichia coli* and *B. subtilis* bacteria	732
Di-*n*-octyl phthalate	Number of colonies	*E. coli* and *B. subtilis* bacteria	732
Detergents, surfactants			
Octylphenol	Cell number	MCF7 breast cancer cells	716
	Dopamine uptake	Fetal hypothalamic cells (primary)	717
	pERK levels	GH3/B6/F10 pituitary cells	718
	hCG-stimulated testosterone levels	Leydig cells (primary)	733
Propylphenol	pERK levels	GH3/B6/F10 pituitary cells	718
Nonylphenol	pERK levels, prolactin release	GH3/B6/F10 pituitary cells	41, 718
	β-Hexosaminidase release	HMC-1 mast cells	720
	Cell number	MCF7 breast cancer cells	135
PAH			
Phenanthrene	All-trans retinoic acid activity	P19 embryonic carcinoma cells	734, 735
Benz(a)acridine	All-trans retinoic acid activity	P19 embryonic carcinoma cells	734
Naphthalene	hCG-stimulated testosterone	Pieces of goldfish testes	736
B-naphthoflavone	hCG-stimulated testosterone	Pieces of goldfish testes	736
Retene	hCG-stimulated testosterone	Pieces of goldfish testes	736
Heavy metals			
Lead	Estrogen, testosterone, and cortisol levels	Postvitellogenic follicles (isolated from catfish)	737
Cadmium	Expression of angiogenesis genes	Human endometrial endothelial cells	738

Due to space concerns, we have not elaborated on the shape of the curve (U, inverted U, or other nonmonotonic shape) or the magnitude of observed effects in this table. DEHP, Bis(2-ethylhexyl) phthalate; DHT, dihydrotestosterone; LDH, lactate dehydrogenase; PCB, polychlorinated biphenyl; PDGF, platelet-derived growth factor.

experiments, chemicals with many different modes of action generate NMDRCs in treated animals.

Perhaps most striking is the range of endpoints affected, from higher-order events such as the number of viable offspring (which could be due to alterations in the reproductive tissues themselves or the reproductive axis), to behavioral effects, to altered organ weights, and to lower-order events such as gene expression. The mechanisms responsible for these nonmonotonic phenomena may be similar to those studied in cell culture systems, although additional mechanisms are likely to be operating *in vivo* such as alterations in tissue organization (541) and the interactions of various players in the positive and negative feedback loops of the endocrine system.

3. Examples of NMDRCs in the epidemiology literature

Perhaps not surprisingly, natural hormones produce NMDRCs in human populations as well (Table 8). Although the methods needed to detect NMDRCs in humans are specific to the field of epidemiology, these results sup-

TABLE 8. NMDRCs for natural hormones identified in the epidemiology literature

Hormone	Affected endpoint	NMDRC	Study subjects	Refs.
Testosterone (free)	Incidence of coronary events	Incidence of 25% at extremes of exposure, 16% at moderate exposure	Rancho Bernardo Study participants, women aged 40+ (n = 639)	824
	Depression	Hypo- and hypergonadal had higher depression scores than those with intermediate free testosterone	Androx Vienna Municipality Study participants, manual workers, men aged 43–67 (n = 689)	825
PTH	Mortality	~50% excess risk for individuals with low or high iPTH	Hemodialysis patients (n = 3946)	826
	Risk of vertebral or hip fractures	~33% higher for low or high iPTH compared to normal levels	Elderly dialysis patients (n = 9007)	827
TSH	Incidence of Alzheimer's disease	About double the incidence in lowest and highest tertile in women (no effects observed in men)	Framingham Study participants (elderly) (n = 1864, 59% women)	828
Leptin	Mortality	Mortality ~10% higher for lowest and highest leptin levels	Framingham Heart Study participants (elderly) (n = 818, 62% women)	563
Insulin	Coronary artery calcification	Higher for low and high insulin area under the curve measures.	Nondiabetic patients with suspected coronary heart disease, cross-sectional (n = 582)	829
	Mortality (noncardiovascular only)	Relative risk ~1.5 for highest and lowest fasting insulin levels	Helsinki Policemen Study participants, men aged 34–64 (n = 970)	830
Cortisol	BMI, waist circumference	Low cortisol secretion per hour for individuals with highest and lowest BMI, waist circumference	Whitehall II participants, adults, cross-sectional (n = 2915 men; n = 1041 women)	831
	Major depression (by diagnostic interview)	Slight increases at extremes of cortisol	Longitudinal Aging Study Amsterdam participants, aged 65+, cross-sectional (n = 1185)	832

BMI, Body mass index; iPTH, intact PTH; PTH, parathyroid hormone.

port the idea that NMDRCs are a fundamental feature of hormones. Importantly, it should be noted that most of the individuals surveyed in studies examining the effects of natural hormones have a disease status or are elderly. This of course does not mean that natural hormones induce NMDRCs in only these select populations but may instead be a reflection of the types of individuals available for these studies (for example, there are very few clinical events in younger people).

NMDRCs observed in the epidemiology literature from human populations exposed to EDCs are now starting to receive attention (Table 9). Here, most reports of NMDRCs come from studies of healthy individuals exposed to persistent organic pollutants POPs, chemicals that do not easily degrade and consequently bioaccumulate in human and animal tissues (542). These POPs do encompass a range of chemical classes including components of plastics, pesticides, and industrial pollutants. A large number of these studies have focused on endpoints that are relevant to metabolic disease, and together, these studies show that there is a recurring pattern of NMDRCs related to POPs and disease. Of course, not every study of POPs shows NMDRCs, and this is probably due to the distribution of EDCs in the populations examined.

In addition to the studies that show strong evidence for NMDRCs in human populations, there is also a subset of studies that provide suggestive evidence for nonmonotonic relationships between EDCs and human health endpoints (Table 9). In fact, the authors of many of these papers clearly identify U- or inverted U-shaped dose-response curves. However, when authors do not perform the appropriate statistical tests to verify the presence of a NMDRC, there is some ambiguity in their conclusions. The usual cross-sectional *vs.* prospective design dichotomy in epidemiology also is a factor that can influence the strength of a NMDRC, or prevent the detection of one at all. This disjunction in design is often incongruous with EDC exposure studies because we often know very little about clearance rates of the chemical, interactions with adiposity, and changes to these factors with age and gender. Yet regardless of any possible weaknesses in these studies, they provide supportive evidence that NMDRCs are observed in human populations.

Because these reports of NMDRCs in human populations are relatively new, few mechanisms have been proposed for these phenomena. Why would risk curves be nonmonotonic over the dose distribution observed in human populations? Why would individuals with the highest exposures have less severe health outcomes compared with individuals with more moderate exposures? One plausible explanation is that the same mechanisms for NMDRCs in animals and cell cultures operate in human populations: chronic exposures to high doses can activate negative feedback loops, activate receptors that promote changes in different pathways that diverge on the same endpoint with opposing effects, or produce some measure of toxicity. Accidental exposures of very large doses may not behave the same as background doses for a variety of reasons, including the toxicity of high doses; these large doses tend to occur over a short time (and therefore more faithfully replicate what is observed in animal studies after controlled administration).

Another explanation is that epidemiology studies, unlike controlled animal studies, examine truly complex mixtures of EDCs and other environmental chemicals. Some chemical exposures are likely to be correlated due to their sources and their dynamics in air, water, soil, and living organisms that are subsequently eaten. Therefore, intake of these chemicals may produce unpredicted, likely nonlinear outcomes whether the two chemicals act via similar or different pathways.

The design of observational epidemiological studies is fundamentally different from studies of cells or animals, in that the EDC exposure distributions are given, rather than set by the investigator. In particular, as shown in Fig. 5, different epidemiological populations will have different ranges of exposure, with the schematic example showing increasing risk in a population with the lowest exposures (labeled group A), an inverted U-shaped risk in a moderate dose population (labeled group B), and an inverse risk in a population with the highest exposures (labeled group C). An additional example is provided (labeled group D) in which an industrial spill shows high risk, but the comparison with the entire unaffected population with a wide variety of risk levels due to differential background exposure could lead to a high- or a low-risk reference group and a wide variety of possible findings.

It is reasonable to suggest that even though epidemiological studies are an assessment of exposures at a single time point, many of these pollutants are persistent, and therefore a single measure of their concentration in blood may be a suitable surrogate for long-term exposures. The movement of people from relatively low- to higher-exposure groups over time depend on refreshed exposures, clearance rates, and individual differences in ability to handle exposures (*i.e.* due to genetic susceptibilities, amount of adipose tissue where POPs can be stored, *etc.*).

Figure 5 therefore further illustrates that observational epidemiological studies yield the composite effect of varying mixtures of EDCs at various exposure levels for various durations, combining acute and chronic effects. These studies are important, however, in that they are the only way to study EDC effects in the long term in intact humans, as opposed to studying signaling pathways, cells,

TABLE 9. NMDRCs for EDCs identified in the epidemiology literature

Chemicals by chemical class	Affected endpoint	NMDRC	Study subjects	Refs.
Insecticides				
Trans-nonachlor	Diabetes incidence	Highest risk in groups with intermediate exposures (quartile 2)	CARDIA participants, case-control study (n = 90 cases and n = 90 controls)	833
	Telomere length in peripheral leukocytes	Increased length in intermediate exposures (quintile 4)	Adults aged 40+ (Korea, n = 84)	591
p,p′-DDE	BMI, triglyceride levels, HDL cholesterol	Highest risk in groups with intermediate exposures (quartile 3)	CARDIA participants (n = 90 controls from nested case control study)	590
	Risk of rapid infant weight gain	For infants born to women of normal weight prepregnancy, risk is highest with intermediate exposures.	Infants from Childhood and the Environment project, Spain (n = 374 from normal prepregnancy weight mothers; n = 144 from overweight mothers)	834
	Telomere length in peripheral leukocytes	Increased length with intermediate exposures (quintile 4)	Adults aged 40+ (Korea, n = 84)	591
Oxychlordane	Bone mineral density of arm bones	With low exposures, fat mass had inverse associations with bone mineral density; with high exposures, fat mass had positive associations with bone mineral density.	NHANES 1999–2004 participants, aged 50+ (n = 679 women, n = 612 men)	835
Plastics				
Mono-methyl phthalate (MMP)	Atherosclerotic plaques	Increased risk in intermediate exposure groups (quintiles 2–4)	Adults aged 70, living in Sweden (n = 1016)	836
Perfluorinated compounds				
PFOA	Arthritis (self-reported)	Increased risk in intermediate exposure groups (quartile 2)	NHANES participants, aged 20+ (both sexes, n = 1006)	837
Fire retardants				
PBB-153	Blood triglyceride levels	Increased risk in intermediate exposure groups (quartile 2)	NHANES participants, aged 12+ (n = 637)	604
PBDE-153	Prevalence of diabetes,	Prevalence of diabetes highest in intermediate groups (quartiles 2–3 relative to individuals with undetectable levels)	NHANES participants, aged 12+ (n = 1367)	604
	Prevalence of metabolic syndrome, levels of blood triglycerides	Prevalence of metabolic syndrome highest in intermediate exposure groups (quartile 2 relative to individuals with undetectable levels); blood triglycerides highest in low exposure groups (quartile 1 relative to individuals with undetectable levels)	NHANES participants, aged 12+ (n = 637)	604
PCB				
PCB-74	Triglyceride levels	Lowest levels are observed in intermediate groups (quartile 2)	CARDIA participants (n = 90 controls from nested case-control study)	590
PCB-126	Bone mineral density in right arm	With low exposures, fat mass had inverse associations with bone mineral density; with high exposures, fat mass had positive associations with bone mineral density	NHANES participants, aged <50 (n = 710 women, n = 768 men)	835
PCB-138	Bone mineral density in right arm	With low exposures, fat mass had inverse associations with bone mineral density; with high exposures, fat mass had positive associations with bone mineral density	NHANES participants, women aged 50+ (n = 679 women, n = 612 men)	835
PCB-153	Telomere length in peripheral leukocytes	Increased length with intermediate exposure groups (quintile 4)	Adults aged 40+ (Korea, n = 84)	591
PCB-170	Diabetes incidence	Highest risk in groups with intermediate exposures (quartile 2)	CARDIA participants, case-control study (n = 90 cases and n = 90 controls)	833
	Endometriosis	Decreased risk in groups with intermediate exposures (quartile 3)	Participants from the Women at Risk of Endometriosis (WREN) study, 18–49 yr old, case-control study (n = 251 cases; n = 538 controls)	838
PCB-172	DNA hypomethylation (by Alu assay)	Highest levels of hypomethylation in groups with lowest and highest exposures	Adults aged 40+ (Korea, n = 86)	839
PCB-180[a]	BMI	Highest BMI with intermediate exposures (quartile 2)	CARDIA participants (n = 90 controls from nested case control study)	590
PCB-187[a]	HDL cholesterol levels	Lowest levels with intermediate exposures (quartile 2)	CARDIA participants (n = 90 controls from nested case control study)	590
PCB 196–203	Diabetes incidence	Highest risk in groups with intermediate exposures (quartile 2)	CARDIA participants, case-control study (n = 90 cases and n = 90 controls)	833
PCB-196	Endometriosis	Decreased risk in groups with intermediate exposures (quartile 3)	Participants from the Women at Risk of Endometriosis (WREN) study, 18–49 yr old, case-control study (n = 251 cases; n = 538 controls)	838

TABLE 9. Continued

Chemicals by chemical class	Affected endpoint	NMDRC	Study subjects	Refs.
PCB-199[a]	Triglyceride levels	Highest risk in groups with intermediate exposures (quartiles 2–3)	CARDIA participants (n = 90 controls from nested case control study)	590
PCB-201	Endometriosis	Decreased risk in groups with intermediate exposures (quartiles 2–3)	Participants from the Women at Risk of Endometriosis (WREN) study, 18–49 yr old, case-control study (n = 251 cases, n = 538 controls)	838
Heavy metals				
Selenium	Fasting glucose levels (by modeled exposure)	Intermediate exposures have highest fasting glucose levels	NHANES 2003- 2004 participants, aged 40+ (n = 917)	840
	Glycosylated hemoglobin (by modeled exposure)	Intermediate exposures have highest % glycosylated hemoglobin	NHANES 2003- 2004 participants, aged 40+ (n = 917)	840
	Diabetes incidence (by modeled exposure)	Intermediate exposures have highest risk for diabetes	NHANES 2003- 2004 participants, aged 40+ (n = 917)	840
	Blood triglyceride levels	Intermediate exposures have highest triglyceride levels	NHANES participants, aged 40+ (n = 1159)	841
Arsenic	Cytokines in umbilical cord blood	Lower inflammatory markers at intermediate exposures (quartile 2)	Pregnant women in Bangladesh (n = 130)	842
Manganese	Mental development scores in infants and toddlers	Intermediate exposures had highest mental development scores at 12 months of age; association lost in older toddlers	12-month-old infants, Mexico (n = 301)	843
	Sperm count, motility and morphology	Intermediate doses had lowest sperm counts and motility; intermediate doses also had the worst sperm morphologies	Men aged 18–55 (infertility clinic patients, n = 200)	844
Mixtures				
31 POP	Diabetes incidence	Highest incidence in intermediate groups (sextiles 2–3)	CARDIA participants, case-control study (n = 90 cases and n = 90 controls)	833
16 POP	Diabetes incidence	Highest incidence in intermediate groups (sextiles 2–3)	CARDIA participants, case-control study (n = 90 cases and n = 90 controls)	833
Non-dioxin-like PCB (mix)	Metabolic syndrome	Highest incidence in intermediate groups (quartile 3)	NHANES 1999–2002 participants, aged 20+ (n = 721)	845
Dioxin-like PCB (mix)	Triacylglycerol levels by quartile of exposure	Highest levels in intermediate groups (quartile 3)	NHANES 1999–2002 participants, aged 20+ (n = 721)	845
Additional supportive evidence for NMDRC in the epidemiology literature				
Insecticides				
Heptachlor epoxide	Prevalence of newly diagnosed hypertension	Highest risk in intermediate groups (quartile 2); other endpoints do not have NMDRC	NHANES participants, women aged 40+, cross-sectional (n = 51 cases, n = 278 total)	26
β-Hexachloro-cyclohexane	Triacylglycerol levels by quartile of exposure	Highest risk in intermediate group (quartile 2)	NHANES participants, aged 20+ (n = 896 men, 175 with metabolic syndrome)	845
Plastics				
Mono-*N*-butyl phthalate (MBP)	BMI, age-specific effects	Effects seen only in elderly participants (age 60–80); risk is lowest in quartile 3	NHANES male participants (n = 365; age 60–80)	470
Mono-benzyl phthalate (MBzP)	BMI, age-specific effects	Effects seen only in young participants (age 6–11); risk is highest in quartiles 2–3	NHANES participants (both sexes, n = 329 males; n = 327 females)	470
Flame retardants				
PFOA	Thyroid disease (self-reported)	Lowest risk in intermediate groups (quartile 3)	NHANES 1999–2000, 2003–2006 participants, males aged 20+ (n = 3974)	837
Dioxin and related compounds				
TCDD	Age at natural menopause	Highest for intermediate exposure group (quintile 4)	Highly exposed women; Seveso Women's Health Study participants (n = 616)	468
HCDD	Bone mineral density in right arm by quintile of fat mass	With low exposures, fat mass had inverse associations with bone mineral density; with high exposures, fat mass had positive associations with bone mineral density	NHANES participants, women aged 50+ (n = 679 women, n = 612 men)	835
Heavy metals				
Selenium	Prevalence of peripheral artery disease	Disease prevalence decreased in intermediate doses, then increased gradually with higher doses	NHANES participants, aged 40+ (n = 2062)	469

organs, or animal models over limited periods of time. Causal inference is not done directly from the epidemiological study results; instead, it is done via combining information from the epidemiological observations with findings from the detailed studies of pathways and animals.

We have suggested that NMDRCs are a fundamental and general feature of hormone action in cells and animals.

Downloaded from https://academic.oup.com/edrv/article-abstract/33/3/378/2354852 by guest on 25 February 2019

Figure 5.

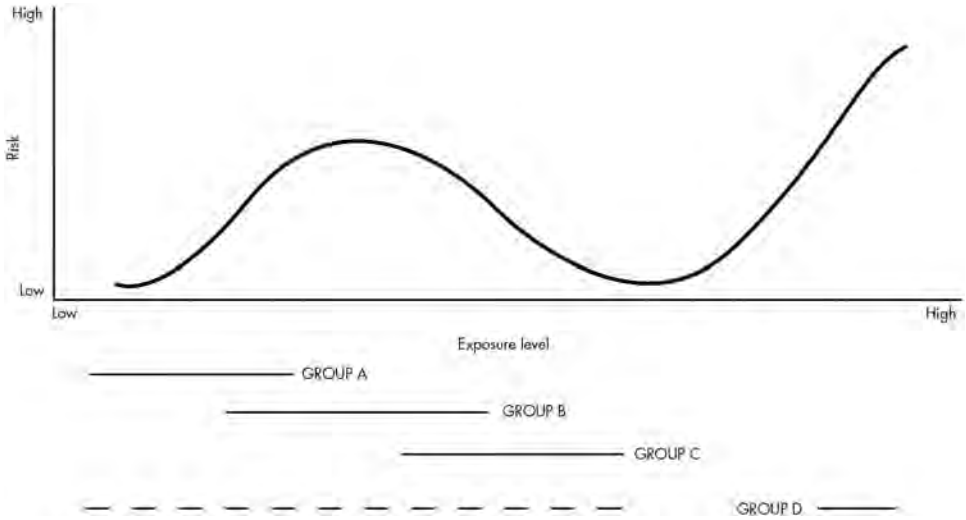

Figure 5. Example of a NMDRC in humans and the sampling populations that could be examined in epidemiology studies. This schematic illustrates a theoretical NMDRC in a human population. If a study were to sample only group A, the conclusion would be that with increasing exposures, risk increases monotonically. Sampling group B would allow researchers to conclude that there is a nonmonotonic relationship between exposure level and risk. If a study included only group C, the conclusion would be that with increasing exposures, there is decreased risk of disease. Group D represents a population that was highly exposed, *i.e.* due to an industrial accident. This group has the highest risk, and there is a monotonic relationship between exposures and risk, although risk is high for all individuals. In the group D situation, there is generally a background population with which high-dose exposure is compared (*dotted line*); relative risk for group D would depend on whether that background population resembles group A, B, or C. From this example, it is clear that the population sampled could strongly influence the shape of the dose-response curve produced as well as the conclusions reached by the study.

It is therefore worth asking whether NMDRCs are expected in the epidemiology literature. The endpoints assessed in epidemiology studies are typically integrated effects, rather than short-term effects; therefore, the various cell- or organ-specific effects may cancel each other, particularly if they are NMDRCs (because they are unlikely to all have nonmonotonicity at the same dose and direction). Thus, NMDRCs are likely to be rarer in the epidemiology literature compared with studies examining the effects of a wide range of doses of an EDC on animals and cultured cells. Yet it is also important to ask what can be concluded if a NMDRC is detected in one epidemiology study but not in others examining the same chemical and outcome. There are several factors that must be considered. The first is that differences in the populations examined between the two studies could explain why a monotonic relationship is observed in one group and a nonmonotonic relationship in another (see Fig. 5). The second is that one or more studies may not be statistically designed to detect NMDRCs. Finally, it is plausible that the NMDRC is an artifact due to residual confounding or some other factor that was not considered in the experimental design. As more becomes known about the mechanisms operating in cells, tissues, and organs to generate NMDRCs, our ability to apply this information to epidemiology studies will increase as well.

4. Tamoxifen flare, a NMDRC observed in cells, animals, and human patients

Although there is controversy in toxicology and risk assessment for endocrine disruptors, NMDRCs are recognized and used in current human clinical practice, although under a different specific term, flare. Flare is often reported in the therapy of hormone-dependent cancers such as breast and prostate cancer. Clinically, failure to recognize the NMDRC that is termed a flare would be considered malpractice in human medicine.

Tamoxifen flare was described and named as a transient worsening of the symptoms of advanced breast cancer, particularly metastases to bone associated with increased pain, seen shortly after the initiation of therapy in some patients (543). If the therapy could be continued, the patients showing tamoxifen flare demonstrated a very high likelihood of subsequent response to tamoxifen, including arrest of tumor growth and progression of symptoms for some time.

The subsequent mechanism of the flare was described in basic lab studies in athymic mouse models of human hormone-dependent breast cancer xenografts (544) and in tissue culture of hormone-dependent human breast cancer cells (545–547). In these models, it was observed that although high, therapeutic concentrations of tamoxifen inhibited estrogen-stimulated proliferation of breast cancer cells, lower concentrations of tamoxifen actually stimulated breast can-

Downloaded from https://academic.oup.com/edrv/article-abstract/33/3/378/2354852 by guest on 25 February 2019

Figure 6.

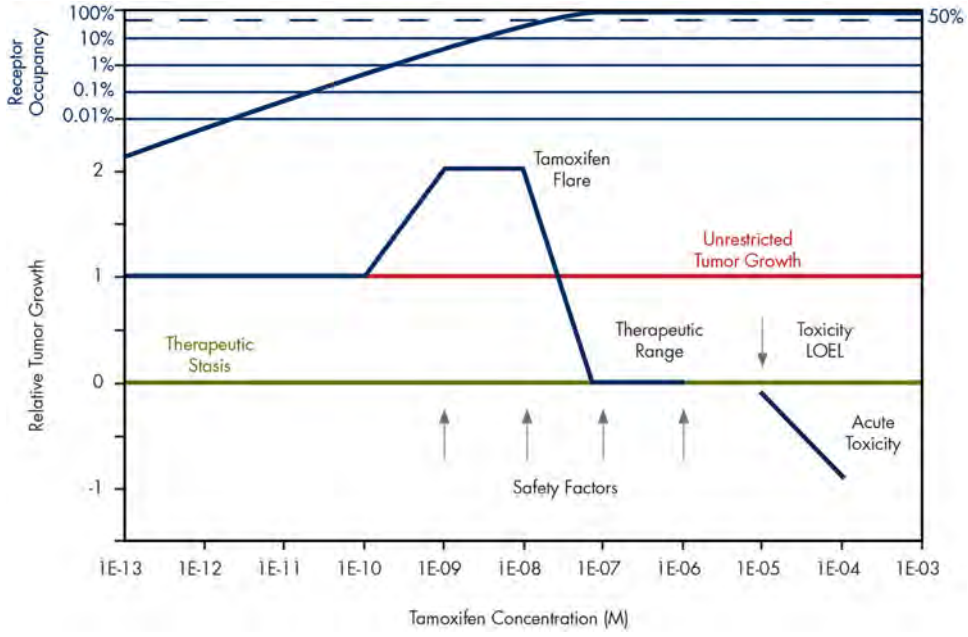

Figure 6. Dose-response ranges for tamoxifen in breast cancer therapy. This figure demonstrates the NMDRC, also called flare, in tamoxifen treatments. As the circulating dose of tamoxifen increases when treatment starts, patients initially experience flare, *i.e.* growth of the tumor (546), followed by a decrease in tumor size as the circulating levels of tamoxifen rise into the therapeutic range (676, 677). High doses of tamoxifen are acutely toxic (546). Starting from the highest concentrations, where acute toxicity is observed, and going to lower concentrations on the X-axis, the acute toxicity diminishes towards zero growth, *i.e.* therapeutic stasis (*green* baseline). This occurs at approximately 1E-05 m, the lowest observed effect level (LOEL) for toxicity. The vertical arrows show the results of applying three or four 10-fold safety factors to the LOEL for the high-dose toxicity of tamoxifen, and would calculate a safe or reference dose for tamoxifen in the region of flare, the least safe region of exposure in actual practice. Above the diagram of dose response ranges is estimated ER occupancy by tamoxifen. This was calculated from the affinity constant of tamoxifen for ERs determined in human breast cancer cells (Ki = 29.1 nM; Ref 678); flare appears to correspond to low receptor occupancy (*blue axis*), therapeutic range with mid and upper-range receptor occupancy, and acute toxicity well above 99% receptor occupancy. (678).

cer cell growth as long as the cells were estrogen dependent (548). Tamoxifen was also shown to disrupt tissue organization of the mammary gland, with specific effects on the stroma that may contribute to the observed effects on proliferation of epithelial cells (549, 550).

Tamoxifen therapy is administered as 10 mg twice per day (20 mg/d; approx 0.3 mg/kg body weight per day), but the target circulating levels are in the near submicromolar range (0.2–0.6 μM); these levels are reached slowly, after approximately 2 wks of therapy (551). In the initial period, where tamoxifen flare is observed, the circulating concentrations are ascending through lower concentrations, in the range below therapeutic suppression of growth, where breast cancer cell proliferation is actually stimulated by the drug, both in tissue culture, in animal xenograft studies, and in human patients (reviewed in Ref. 548). The recognition of this dual dose-response range for tamoxifen (low-dose, low-concentration estrogenic growth-stimulatory and higher-dose, higher-concentration estrogenic growth-inhibitory responses) led to the definition of the term selective estrogen response modulator, or SERM, activity (552–554). This SERM activity has since been observed for many or even most estrogenic EDCs, including BPA (3, 555–557).

These observations defined three separate dose-response ranges for the SERM tamoxifen in human clinical use. The lowest dose-response range, the range of flare, stimulated breast cancer growth and symptoms in some patients with hormone-dependent cancer. The next higher dose-response range is the therapeutic range where tamoxifen inhibits estrogen-dependent tumor growth. The highest dose range causes acute toxicity by the SERM (see Fig. 6).

Tamoxifen provides an excellent example for how high-dose testing cannot be used to predict the effects of low doses. For tamoxifen (as for other drugs), the range of acute human toxicity for tamoxifen was determined in phase I clinical trials. Phase I trials also defined an initial therapeutic range, the second dose-response range, as a dose below which acute toxicity was not observed. The therapeutic dose range was tested and further defined in phase II and later clinical trials to determine efficacy (see for example Ref. 558). Standard toxicological testing from

Figure 7.

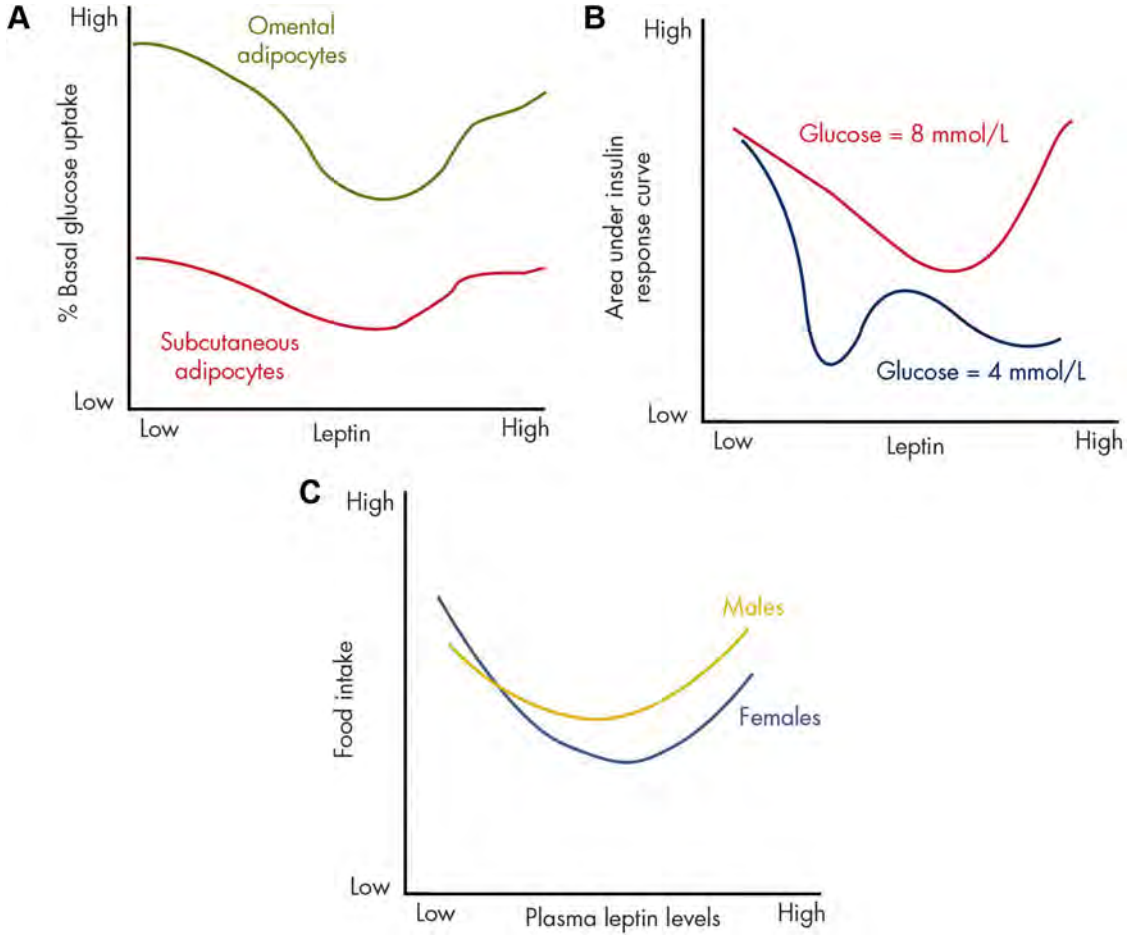

Figure 7. Leptin as an example of a NMDRC. Several studies report NMDRCs in response to leptin treatments. A, NMDRCs are observed in cultured primary adipocytes after leptin exposure. This graph illustrates the relationship between administered leptin dose and glucose uptake in two types of adipocytes, those isolated from omental tissue (*green*) and others from sc fat (*purple*) (schematic was made from data in Ref. 559). These data are on a log-linear plot. B, *Ex vivo* rat pancreas was treated with leptin and various doses of glucose, and the insulin response curves were examined. Area under the curve is a measure of the ability of the pancreas to bring glucose levels under control. Different dose-response curves were observed depending on the amount of glucose administered: a U-shaped curve when 8 mmol/liter was included (*pink*) or a multiphasic curve with 4 mmol/liter (*blue*) (schematic made from data in Ref. 560). These data are on a linear-linear plot. C, U-shaped NMDRCs were also observed when food intake was compared with leptin levels in the blood of rats administered the hormone. This response was similar in males (*orange*) and females (*cyan*) (schematic made from data in Ref. 562). These data are on a linear-linear plot.

high doses to define a LOAEL or NOAEL are equivalent to the phase I clinical testing, and in risk assessment, a safe dose or reference dose is calculated from these tests. However, the lowest dose range, with the highly adverse effects termed flare, was not detected in the phase I trials and was determined only for tamoxifen in breast cancer therapy at the therapeutic doses (543). The implication for risk assessment is that NMDRCs for EDCs, particularly those already identified as SERMs, would likely not be detected by standard toxicological testing at high doses. That is, the consequence of high-dose testing is the calculation of a defined but otherwise untested safe dose that is well within the range equivalent to flare, *i.e.* a manifestly unsafe dose of the EDC (Fig. 6).

5. Similarities in endpoints across cell culture, animal, and epidemiology studies: evidence for common mechanisms?

There are common trends in some findings of NMDRCs in cell, animal, and human studies and therefore evidence for related mechanisms for NMDRCs at various levels of biological complexity. Tamoxifen flare, discussed in *Section III.C.4*, is an informative example. Another illustrative example is that of the effect of the hormone leptin (Fig. 7). In cultured primary adipocytes, NMDRCs are observed after leptin exposure; moderate doses of leptin significantly reduce insulin-mediated glucose intake, whereas low and high doses maintain higher glucose intake in response to insulin (559). The rat pancreas shows a similar response to leptin; the amount of

Downloaded from https://academic.oup.com/edrv/article-abstract/33/3/378/2354852 by guest on 25 February 2019

secreted insulin has an inverted U-shaped response to leptin (560, 561). Even more striking is the relationship between leptin and food intake. Rats administered moderate doses of leptin consume less food compared to rats dosed with low or high levels of leptin (562); mechanistically, this lower food intake could be due to higher circulating glucose levels in these animals due to ineffective insulin action. And finally, in a human study, leptin levels were found to correlate with body mass index but have a U-shaped relationship with mortality (563). These results suggest that hormones can produce similar responses at several levels of biological complexity (cell, organ, animal, and population).

A large number of epidemiology studies with NMDRCs have found relationships between EDC exposures like POPs and metabolic diseases including obesity and diabetes (Table 9) (see also Ref. 564 for a review), and the mechanisms for these relationships have begun to be explored. Human and animal cells treated with EDCs in culture display NMDRCs that are relevant to these diseases: BPA has nonmonotonic effects on the expression of adipocyte proteins in preadipocytes and the release of adiponectin from mature adipocytes (565–567). Similarly, in female rodents, low doses but not high doses of BPA increased adipose tissue weight and serum leptin concentrations (568), and intermediate doses of phthalates decrease serum cholesterol levels (569). Thus, although understanding the mechanisms operating at the cellular level of organization has not yet led to definitive knowledge of the mechanisms producing NMDRCs in human populations, there appear to be strong similarities in cells, animals, and humans that support a call for continued work focusing on metabolic disease endpoints at each level of biological organization.

D. NMDRC summary

We have demonstrated that nonmonotonicity is a common occurrence after exposures to hormones and EDCs in cell culture and animals and across human populations. Because of the abundance of examples of NMDRCs, we expect that if adequate dose ranges are included in animal and cell culture studies, including the use of negative and well-chosen positive controls, NMDRCs may be observed more often than not. Here, we have focused mainly on studies that examined a wide range of doses, including many that examined the effects of doses that span the low-dose and toxicological ranges. We also discussed several mechanisms that produce NMDRCs. Each of these mechanisms can and does operate at the same time in a biological system, and this cooperative action is ultimately responsible for NMDRCs.

Understanding nonmonotonicity has both theoretical and practical relevance. When a chemical produces monotonic responses, all doses are expected to produce similar effects whose magnitude varies with the dose, but when a chemical produces a NMDRC, dissimilar or even opposite effects will be observed at different doses. Thus, monotonic responses can be modeled using the assumption that each step in a linear pathway behaves according to the law of mass action (43, 570); high doses are always expected to produce higher responses. In contrast, NMDRCs are not easy to model (although they are quite easy to test for), requiring detailed knowledge of the specific mechanisms operating in several biological components. From a regulatory standpoint, information from high doses cannot always be used to assess whether low doses will produce a biological effect (38).

IV. Implications of Low-Dose Effects and Nonmonotonicity

Both low-dose effects and NMDRCs have been observed for a wide variety of EDCs as well as natural hormones. Importantly, these phenomena encompass every level of biological organization, from gene expression, hormone production, and cell number to changes in tissue architecture to behavior and population-based disease risks. One conclusion from this review is that low-dose effects and NMDRCs are often observed after administration of environmentally relevant doses of EDCs. For both hormones and EDCs, NMDRCs should be the default assumption absent sufficient data to indicate otherwise. Furthermore, there are well-understood mechanisms to explain how low-dose effects and NMDRCs manifest *in vitro* and *in vivo*. Accepting these phenomena, therefore, should lead to paradigm shifts in toxicological studies and will likely also have lasting effects on regulatory science. Some of these aspects are discussed below. Additionally, we have briefly explored how this knowledge should influence future approaches in human and environmental health.

At a very practical level, we recommend that researchers publishing data with low-dose and nonmonotonic effects include key words in the abstract/article that identify them as such specifically. This review was unquestionably impeded because this has not been standard practice. We also strongly recommend that data showing nonmonotonic and binary response patterns not be rejected or criticized because there is no dose response.

A. Experimental design

1. Dose ranges must be chosen carefully

To detect low-dose effects or NMDRCs, the doses included for testing are of utmost importance. Most of the studies we examined here for nonmonotonicity tested

Downloaded from https://academic.oup.com/edrv/article-abstract/33/3/378/2354852 by guest on 25 February 2019

doses over severalfold concentrations. Unfortunately, regulatory guidelines only require that three doses be tested. Both low-dose effects and NMDRCs can be observed when examining only a few doses, but some studies may detect significant results purely by luck, because a small shift in dose can have a large impact on the ability to observe differences relative to untreated controls.

In the multitude of chemicals that have never been tested at low doses, or in the development of new chemicals, to determine whether a chemical has low-dose effects in laboratory animals, we suggest setting the NOAEL or LOAEL from traditional toxicological studies as the highest dose in experiments specifically designed to test endocrine-sensitive endpoints. We suggest setting the lowest dose in the experiment below the range of human exposures, if such a dose is known. Several intermediate doses overlapping the range of typical human exposures should be included also, bringing the total number in the range of five to eight total doses tested. Importantly, although the levels of many environmental chemicals in human blood and/or urine have been reported by the CDC and other groups responsible for population-scale biomonitoring, it is often not known what administered doses are needed to achieve these internal exposure levels in animals (4, 253); thus, toxicokinetic studies are often needed before the onset of low-dose testing. This is important because the critical issue is to determine what effects are observed in animals when circulating levels of an EDC match what is measured in the typical human. Due to differences in metabolism, route of exposure, and other factors, a relatively high dose may need to be administered to a rodent to produce blood concentrations in the range of human levels; however, this should not be considered a high-dose study.

It has also been suggested that animal studies that are used to understand the potential effects of a chemical on humans should use a relevant route of administration to recapitulate human exposures (571, 572) because there may be differences in metabolism after oral and nonoral administration. Many chemicals that enter the body orally undergo first-pass metabolism and are then inactivated via liver enzymes, whereas other routes (*i.e.* sc) can bypass these mechanisms and lead to a higher concentration of the active compound in circulation (573). Studies indicate, however, that inactivation of chemicals via first-pass metabolism is not complete and also that deconjugation of metabolites can occur in some tissues allowing the rerelease of the active form (574, 575). Additionally, for some chemicals, it is clear that route of administration has little or no impact on the availability of the active compound in the body (241, 384), and other studies show that route of administration has no impact on the biological effects of these chemicals; *i.e.* regardless of how it enters the body, dioxin has similar effects on exposed individuals (384), and comparable results have been observed for BPA (141). Although understanding the typical route of human exposure to each environmental chemical is an important task, it has been argued that any method that leads to blood concentrations of a test chemical in the range they are observed in humans is an acceptable exposure protocol, and this is especially true with gestational exposures, because fetuses are exposed to chemicals only via their mothers' blood (31, 576).

2. Timing of exposures is important

Rodent studies indicate that EDC exposures during development have organizational effects, with permanent effects that can manifest even in late adulthood, whereas exposures after puberty are for the most part activational, with effects that are abrogated when exposures cease. For example, the adult uterus requires relatively large doses of BPA (in the parts-per-million range) to induce changes associated with the uterotrophic assay (555, 577), whereas parts-per-trillion and ppb exposures during the fetal period permanently and effectively alter development of the uterus (279, 310, 578). Thus, the timing of exposures is profoundly important to detect low-dose effects of EDCs.

Human studies also support this conclusion. The 1976 explosion of a chemical plant in Seveso, Italy, which led to widespread human exposure to large amounts of TCDD, a particularly toxic form of dioxin, and the deposition of this chemical on the land surrounding the chemical plant, provided evidence in support of the organizational and activational effects of endocrine-active chemicals in humans (579). Serum TCDD concentrations showed correlations between exposure levels and several disease outcomes including breast cancer risk, abnormal menstrual cycles, and endometriosis (580–582), but individuals who were either infants or teenagers at the time of the explosion were found to be at greatest risk for developing adult diseases (583, 584). Importantly, many scientists have argued that organizational effects can occur during puberty, *i.e.* that the period where hormones have irreversible effects on organ development extends beyond the fetal and neonatal period (585), and for some endpoints this appears to be the case (586, 587).

It has also been proposed that the endocrine system maintains homeostasis in the face of environmental insults (210). The adult endocrine system does appear to provide some ability to maintain a type of homeostasis; when the pharmaceutical estrogen DES is administered to pregnant mice, the circulating estradiol concentrations in the dam respond by decreasing linearly (224). In contrast, fetal concentrations of estradiol respond nonmonotonically in

Downloaded from https://academic.oup.com/edrv/article-abstract/33/3/378/2354852 by guest on 25 February 2019

a way that is clearly not correlated with maternal levels. Similarly, there is evidence that BPA can induce aromatase and therefore increase estradiol levels *in situ* in the fetal urogenital sinus (588). This is an example of a feed-forward positive-feedback effect rather than a homeostatic response. The effects of EDCs on adult subjects, both animal and people, suggest that diseases often result from low-dose adult exposures (589–595); this argues against a view of the endocrine system as a means to maintain homeostatic control. Instead, individuals can be permanently changed, in an adverse way, after EDC exposures.

In one example, pregnant mice were exposed to low concentrations of BPA, and their male offspring had altered pancreatic function at 6 months of age (158). Surprisingly, however, the mothers (exposed only during pregnancy) were also affected, with altered metabolic machinery and body weight at 4 months postpartum, long after exposures had ended. The increased incidence of breast cancer in women that took DES during pregnancy also illustrates this point (596, 597). These studies suggest that even the adult endocrine system is not invariably capable of maintaining a so-called homeostatic state when exogenous chemicals affecting the endocrine system are present. Thus, although adult exposures to EDCs have been given some attention by bench scientists (29), more work of this kind is needed to better understand whether and how EDCs can have permanent organizational effects on adult animals.

At the beginning of this review, we justified the need to critically examine the low-dose literature because of recent epidemiological findings linking EDC exposures and diseases. Yet there is inherent difficulty in examining neonatal exposures to EDCs and their connection to diseases due to the length of time needed for these studies; thus, many studies of this type have examined high doses of pharmaceuticals (*i.e.* DES) or accidental exposures to industrial chemicals (*i.e.* dioxin) (66, 398, 399, 581, 597–601).

Only recently, with the availability of biomonitoring samples from large reference populations, have lower doses begun to receive widespread attention from epidemiologists. Many recent studies have examined adult exposures to EDCs and correlated exposures with disease statuses (see for example Refs. 15, 16, and 602–604). Human studies examining fetal/neonatal exposures to low-dose EDCs and early life effects have also begun to be studied (6, 333, 605–607), although studies linking these early life exposures to adult diseases are likely to be decades away. More than anything, these studies support our view that the effects of low-dose exposures should be considered when determining chemical safety.

3. Importance of endpoints being examined

Traditional toxicology testing, and in particular those studies performed for the purposes of risk assessment, typically adhere to guideline studies that have been approved by international committees of experts (608). The endpoints assessed in these guideline-compliant studies are centered around higher-order levels, including weight loss, mortality, changes in organ weight, and a limited number of histopathological analyses (609, 610). When pregnant animals are included in toxicological assessments, the endpoints measured typically include the ability to maintain pregnancies, the number of offspring delivered, sex ratios of surviving pups, and measures regarding maternal weight gain and food/water intake (610).

Yet low-dose EDCs are rarely toxic to the point of killing adult animals or causing spontaneous abortions, and traditional tests such as the uterotrophic assay have been shown to be relatively insensitive (72, 577). It has been argued that this type of testing is insufficient for understanding the effects of EDCs (31, 70, 495, 611). Many EDC studies have instead focused on examining newly developed, highly sensitive endpoints that span multiple levels of biological organization, from gene expression to tissue organization to organ systems to the whole animal (612), which may not be rapidly lethal but which nonetheless have enormous importance for health, including mortality. Thus, for example, studies designed to examine the effects of chemicals on obesity no longer focus on body weight alone but also analyze gene expression; fat content in adipose cells and the process of adipogenesis; inflammation, innervation, and vascularization parameters in specific fat pads; conversion rates of white and brown adipose tissues; systemic hormone levels and response to glucose and insulin challenges; and food intake and energy expenditures, among others (314, 613–615). As our knowledge of EDCs and the endocrine system continue to grow, the most sensitive endpoints should be used to determine whether a chemical is disrupting the development of organisms (70).

In moving beyond traditional, well-characterized health-related endpoints like mortality and weight loss, an important question has been raised: how do we define endpoints as adverse? This is an important point, because it has been suggested that the endpoints examined in independent EDC studies are not validated and may not represent adverse effects (609). There is also debate over whether the mechanism (or mode) of action must be explained for each effect to determine whether a relevant pathway is present in humans (616, 617). Yet, when originally assessing the low-dose literature, the NTP expert panel chose to examine all effects of EDC exposure, re-

Downloaded from https://academic.oup.com/edrv/article-abstract/33/3/378/2354852 by guest on 25 February 2019

gardless of whether the endpoint could be deemed adverse (2). From the perspective of developmental biology, any change in development should be seen as adverse, even if the change itself is not associated with a disease or dysfunction. Some of these developmental changes, in fact, may increase sensitivity or susceptibility to disease later on in life but will otherwise appear normal. Furthermore, studies of heavy metals have shown that small shifts in parameters like IQ may not have drastic effects on individuals but can have serious repercussions on the population level (618), and therefore changes in the variance/observable range of a phenotype should also be considered adverse (52).

4. Importance of study size

National Institutes of Health guidelines require that the number of vertebrate animals used in experiments be as small as possible to show statistically significant effects based on power analysis. Yet many traditional toxicology studies have used large numbers of animals to draw conclusions about chemical safety. When the endpoints being assessed have binary outcomes (*i.e.* animal has a tumor *vs.* animal does not have a tumor) and the incidence of the phenotype is not high, a large number of animals is required to reveal statistically significant effects. In contrast, many of the endpoints examined in the field of endocrine disruption are more complex and are not binary; thus, power analysis allows researchers to determine how many animals are needed to observe statistically significant (and biologically relevant) differences between control and exposed populations. For this reason, arbitrary numbers set as cutoffs for determining whether a study is acceptable or unacceptable for risk assessments are not appropriate. Instead, the number of animals required for a study to be complete is dependent on the effect size, precision/variance, minimal meaningful difference to be considered between populations, and the α-value set in statistical tests.

B. Regulatory science

For decades, regulatory agencies have tested, or approved testing, of chemicals by examining high doses and then extrapolating down from the NOAEL, NOEL, and LOAEL to determine safe levels for humans and/or wildlife. As discussed earlier, these extrapolations use safety factors that acknowledge differences between humans and animals, exposures of vulnerable populations, interspecies variability, and other uncertainty factors. These safety factors are informed guesses, not quantitatively based calculations. Using this traditional way of setting safe doses, the levels declared safe are never in fact tested. Doses in the range of human exposures are therefore also unlikely to be tested. This has generated the current state of science, where many chemicals of concern have never been examined at environmentally relevant low doses (see Table 4 for a small number of examples).

Assumptions used in chemical risk assessments to estimate a threshold dose below which daily exposure to a chemical is estimated to be safe are false for EDCs. First, experimental data provide evidence for the lack of a threshold for EDCs (619). More broadly, the data in this review demonstrate that the central assumption underlying the use of high doses to predict low-dose effects will lead to false estimates of safety. The use of only a few high doses is based on the assumption that all dose-response relationships are monotonic and therefore that it is appropriate to apply a log-linear extrapolation from high-dose testing to estimate a safe reference dose (Fig. 4). The Endocrine Society issued a position statement on EDCs (620) and urged the risk assessment community to use the expertise of their members to develop new approaches to chemical risk assessments for EDCs based on principles of endocrinology. Undertaking this mission will represent a true paradigm shift in regulatory toxicology (79). The Endocrine Society statement was then supported in March 2011 by a letter to *Science* from eight societies with relevant expertise representing over 40,000 scientists and medical professionals (621).

Studies conducted for the purposes of risk assessment are expected to include three doses: a dose that has no effects on traditional toxicological endpoints (the NOAEL), a higher dose with effects on traditional endpoints (the LOAEL), and an even higher dose that shows toxicity. Although reducing the number of animals used for these types of studies is an important goal, more than three doses are often needed for a true picture of a chemical's toxicity. The examination of a larger number of doses would allow for 1) the study of chemicals at the reference dose, *i.e.* the dose that is calculated to be safe; 2) examination of doses in the range of actual human exposures, which is likely to be below the reference dose; and 3) the ability to detect NMDRCs, particularly in the low-dose range. The impact of testing more doses on the numbers of animals required can be mitigated by use of power analysis, as suggested above. Because no amount of research will ever match the diversity and reality of actual human experience, there should be ongoing epidemiological study of potential adverse effects of EDCs even after safe levels are published, with periodic reevaluation of those safe levels.

One issue that has been raised by regulatory agencies is whether animal models are appropriate for understanding the effects of EDCs on humans. These arguments largely center around observed differences in hormone levels during different physiological periods in rodents and humans (57), and differences in the metabolic machinery and ex-

Downloaded from https://academic.oup.com/edrv/article-abstract/33/3/378/2354852 by guest on 25 February 2019

cretion of chemicals between species (622). To address the first issue, it should be noted that the FDA uses animals to test pharmaceuticals and other chemicals before any safety testing in humans because it is widely recognized that, although animals and humans do not have exactly the same physiologies, there is evolutionary conservation among vertebrates and specifically among mammals (62). Furthermore, animal studies proved to be highly predictive of the effects of DES on women, indicating that rodents are sufficiently similar to humans to reliably forecast affected endpoints in the endocrine system (64, 623). Thus, the default position must be that animal data are indicative of human effects until proven otherwise.

With regard to the second issue, BPA researchers in particular have examined species-specific differences in metabolism of this EDC. Interestingly, the pharmacokinetics of BPA in rodents, monkeys, and humans appear to be very similar (624), and regulatory agencies have subsequently concluded that rodents are appropriate models to assess the effects of this chemical (625, 626). Thus, researchers should select animal models that are sensitive to low doses of hormones and select appropriate species for the endpoints of interest. As the scope of our knowledge has broadened about how chemicals can alter the endocrine system, well beyond estrogens, androgens, and the thyroid, it is imperative that considerable thought be given to how to apply this for regulatory purposes.

C. Human health

As discussed several times throughout this review, there is now substantial evidence that low doses of EDCs have adverse effects on human health. Thus, although many epidemiological studies originally focused on occupationally exposed individuals and individuals affected by accidental exposures to high doses of environmental chemicals, these recent studies have suggested wide-ranging effects of EDCs on the general population.

Importantly, human exposures are examples of true mixtures; dozens if not hundreds of environmental chemicals are regularly detected in human tissues and fluids (91), yet very little is known about how these chemicals act in combination (627). Several studies indicate that EDCs can have additive or even synergistic effects (143, 323, 628–630), and thus these mixtures are likely to have unexpected and unpredictable effects on animals and humans. The study of mixtures is a growing and complex field that will require considerable attention in the years ahead as knowledge of EDCs in the laboratory setting are applied to human populations (631, 632).

How much will human health improve by testing chemicals at low, environmentally relevant doses and using the results to guide safety determinations? Current testing paradigms are missing important, sensitive endpoints; because they are often unable to detect NMDRCs, they cannot make appropriate predictions about what effects are occurring at low doses. At this time, it is not possible to quantify the total costs of low-dose exposures to EDCs. However, current epidemiology studies linking low-dose EDC exposures to a myriad of health problems, diseases, and disorders suggest that the costs of current low-dose exposures are likely to be substantial.

The weight of the available evidence suggests that EDCs affect a wide range of human health endpoints that manifest at different stages of life, from neonatal and infant periods to the aging adult. As the American population ages, healthcare costs continue to rise, and there are societal costs as well, with decreased quality of life concerns, decreases in work productivity due to illness or the need for workers to care for affected family members, and the psychological stresses of dealing with some outcomes like infertility. Thus, it is logical to conclude that low-dose testing, followed by regulatory action to minimize or eliminate human exposures to EDCs, could significantly benefit human health. This proposal effectively calls for greatly expanded research to give human communities feedback about themselves. It emanates from a view that human society benefits greatly from the many chemical compounds it uses but that extensive epidemiological surveillance and other focused research designs are needed to assure that the balance of risk/benefit from those chemicals is acceptable.

How much would human health benefit by a reduction in the use of EDCs? For some chemicals, minor changes in consumer habits or industrial practices can have drastic effects on exposures (633–636). Other chemicals like DDT that have been regulated in the United States for decades continue to be detected in human and environmental samples; the persistent nature of many of these agents suggests they may impact human health for decades to come. Even less-persistent chemicals like BPA are likely to remain in our environment long after a ban is enacted because of the large amounts of plastic waste leaching BPA (and other estrogenic compounds) from landfills into water sources (637) and its presence on thermal receipt paper and from there into recycled paper (638–640). Yet, despite these challenges, reducing human exposure to EDCs should be a priority, and one way to address that priority is to decrease the production and use of these chemicals. The Endocrine Society has called for such a reduction and the use of the precautionary principle, *i.e.* action in the presence of concerning information but in the absence of certainty to eliminate or cut the use of questionable chemicals even when cause-effect relationships are not yet established (620).

Downloaded from https://academic.oup.com/edrv/article-abstract/33/3/378/2354852 by guest on 25 February 2019

D. Wildlife

Much of the recent focus on EDCs has been on the impact of these chemicals on human health. Yet the earliest studies of EDCs that focused on the impact of these chemicals on wildlife should not be forgotten. Rachel Carson's work on DDT and other pesticides provided some of the earliest warning signs that there were unintended consequences of chemical use. Carson's work was ahead of its time; she understood that exceedingly small doses of these chemicals produced adverse effects, that the timing of exposures was critical, and that chemical mixtures produced compounded effects (641). Now, decades after some of the most dangerous EDCs have been regulated, they continue to be measured in environmental samples as well as the bodies of wildlife animals.

Furthermore, it should be pointed out that humans, like wildlife, are not insulated from the environment, and effects in wildlife, including nonmammalian species, are indicative of and mirror effects in humans. For example, BPA has estrogen-like effects in fish (642–644), amphibians (645, 646), and reptiles (647, 648). A recent review showed that demasculinizing and feminizing effects of atrazine have been demonstrated in fish, amphibians, reptiles, birds, and mammals, *i.e.* every vertebrate class examined (326); and in fact, the first report to suggest that atrazine induced aromatase was conducted in reptiles (649). Similarly, perchlorate affects fish (650–653), amphibians (654–658), and birds (659–661) via mechanisms consistent with those described for humans, and some of the earliest reports on perchlorate's effects on thyroid function were conducted in amphibians (661, 662). Finally, ecological studies of dioxin and dioxin-like chemicals reveal effects on a range of exposed wildlife including birds (663, 664), fish (665, 666), and invertebrates (667). Although these studies have highlighted some of the species-specific effects of dioxin (389), and orders of magnitude differences in toxic equivalency factors between species (668), they also indicate the conservation of mechanisms for the effects of dioxin on a range of biological endpoints in wildlife, laboratory animals, and humans (384). In fact, in many cases, nonmammalian species are much more sensitive to EDC effects, and wildlife species serve as sentinels for environmental and public health (669–673). Thus, the effects of these chemicals on wildlife populations are likely to continue; for this reason, the low-dose effects of these chemicals are particularly worth understanding (674, 675).

V. Summary

In conclusion, we have provided hundreds of examples that clearly show that NMDRCs and low-dose effects are common in studies of hormones and EDCs. We have examined each of these issues separately and provided mechanistic explanations and examples of both. These topics are related, but they must be examined individually to be understood. The concept of nonmonotonicity is an essential one for the field of environmental health science because when NMDRCs occur, the effects of low doses cannot be predicted by the effects observed at high doses. In addition, the finding that chemicals have adverse effects on animals and humans in the range of environmental exposures clearly indicates that low doses cannot be ignored.

In closing, we encourage scientists and journal editors to publish data demonstrating NMDRCs and low-dose effects, even if the exact mechanism of action has not yet been elucidated. This is important because the study of EDC is a growing specialty that crosses many scientific fields, and scientists that work on or regulate EDCs should appreciate and acknowledge the existence of NMDRCs and low-dose effects and have access to this important information. We further recommend greatly expanded and generalized safety testing and surveillance to detect potential adverse effects of this broad class of chemicals. Before new chemicals are developed, a wider range of doses, extending into the low-dose range, should be fully tested. And finally, we envision that the concepts and empirical results we have presented in this paper will lead to many more collaborations among research scientists in academic and government laboratories across the globe, that more and more sophisticated study designs will emerge, that what we have produced herein will facilitate those making regulatory decisions, that actions taken in light of this information will begin to abate the use of EDCs, and ultimately that health impacts in people and in wildlife will be averted.

Acknowledgments

We thank many colleagues in the fields of endocrine disruption and environmental health science for fruitful discussions on the topics covered in this manuscript. We also thank three anonymous reviewers whose comments and suggestions greatly improved this review.

We dedicate this manuscript to Professor Howard A. Bern. Dr. Bern was an exceptionally brilliant biologist and a generous and inspiring colleague. His work spanning a wide range of organisms addressed multiple aspects of organismal and evolutionary biology. He was one of the founders of the field of comparative endocrinology and a pioneer in the study of endocrine disruption, anticipating the deleterious effects of developmental exposure to estrogens one decade before the discovery of the effects of diethylstilbestrol in women fetally exposed to this chemical. His pioneering work included, among other subjects, neuroendocrinology, reproduction, and mammary cancer. He was also an excellent mentor to many researchers who, in turn, advanced these endeavors. He left an indelible mark on all of us that had the privilege of meeting him.

Disclosure Summary: Fred vom Saal worked as a consultant and provided expert testimony (<$10K). The authors have nothing to disclose.

Subject: RE: Test results
To: [redacted]@gmail.com>

Good morning, as attached, please see the sampling results for the raw effluent discharge ditch taken in October and November 2017. Note that the October sampling was during routine mill maintenance. Regards, Ken Swain

Good evening. We are accessing the specific sampling results from our consultant and will forward them to you once we receive them. This will probably be first of next week.

Regards,

Ken Swain

Subject: Test results

I understand that GHD had tests conducted to determine the nature of the raw effluent currently flowing into Boat Harbour. I would like a copy of these tests. Will you please forward them to me? If you are not able to forward them to me, where can I access or obtain them?

Thank you,

Canso Chemicals Site Decommissioning Final Report

We are pleased to present six copies of our final report documenting decommissioning activities at the Canso Chemicals Limited site. The report also documents the results of an ecological and human health risk assessment relative to an area with residual mercury that did not meet the 1993 remedial action plan cleanup objectives. A Certificate of Compliance for the facility has been prepared, under the Nova Scotia Contaminated Sites Management Program, and is included with this report. App-F

It has been a pleasure to work with you on this project. If we can be of further assistance, please contact the undersigned at your convenience.

Yours truly,

DILLON CONSULTING LIMITED

Project Manager

1.0 INTRODUCTION

1.1 Purpose

The purpose of this report is to document remedial activities carried out at Canso Chemicals Limited, located at Abercrombie Point (refer to Figure 1-1). Canso Chemicals Limited is a former chloro-alkali plant, which used mercury in its process to generate chlorine and caustic soda for the pulp and paper industry. Upon ceasing operations at the plant in 1992, a program was put in place to decommission the site, including remediation of environmental contaminants. Included in this report is a description of demolition activities relating to the process building (housing the cell room and brine basement) in 1999 (refer to Figure 1-2).

This report provides an overview of site remedial activities surrounding the processing and chlorate buildings, documents confirmatory sampling completed to demonstrate adherence to generic remedial objectives, and proposes site specific remedial objectives for a limited area of the site, based on an assessment of risk to human health and the environment. Recommendations are made for the long term monitoring of the site.

1.2 Background

Canso Chemicals Limited was formed in 1968. A chloro-alkali plant was commissioned in 1970 at Abercrombie Point to produce bleaching chemicals used in the production of pulp and paper (i.e., liquid chlorine and liquid caustic soda). In 1971 a chlorate plant (producing liquid sodium chlorate) was constructed on the site and was operated until 1981.

In 1992, the chloro-alkali plant was shut down. The site is currently used as a caustic soda shipping and receiving facility.

	PROJECT CANSO CHEMICALS SITE DECOMMISSIONING	PROJECT No. 98-5519
		FIGURE No. 1-1

The products made at Canso Chemicals Limited were the result of the electrolysis of a brine solution over mercury electrolytic cells. The primary contaminant of concern on the site is mercury. During 1973-1975, a series of equipment failures in the cell room resulted in high mercury consumption and mercury was lost to the floor (Canso Chemicals Limited, 1993). After that time a comprehensive mercury inventory was maintained, and mercury losses were more tightly controlled (pers. comm. D. Currie). Mercury was also found in process by-products (e.g., brine sludge), which were managed on-site.

Canso Chemicals Limited submitted a site remedial action plan to Nova Scotia Department of the Environment on June 21, 1993 (Canso Chemicals Limited, 1993). This plan outlined an approach to manage site contaminants, including mercury. The plan established an objective of meeting Canadian Council of Ministers of the Environment (CCME) industrial land use guidelines for soil.

1.3 Regulatory Context

The 1993 remedial action plan (RAP) committed to meeting CCME industrial land use guidelines for soil. The Interim Canadian Environmental Quality Criteria for Contaminated Sites (CCME, 1991) established a remedial objective of 10 mg/kg mercury in soil for commercial/industrial sites. The Recommended Canadian Soil Quality Guidelines (CCME, 1997) adopt 30 mg/kg as the soil quality guideline for mercury at industrial sites, superseding the 1991 guideline.

The Nova Scotia Department of the Environment have established guidelines for management of contaminated sites (NSDOE, 1996). These guidelines outline two approaches to contaminated site management. Tier I requires the owner to remediate the site to guideline concentrations appropriate for the future use of the property. Tier II identifies potential risk by comparing detected concentrations of contaminants with site specific criteria. Site specific criteria are determined by calculating potential adverse effects associated with exposure to contaminants at the concentrations detected on site.

The 1993 RAP adopted a Tier I approach, committing to cleanup the site to CCME industrial land use guidelines. Until June 1999, remedial activities were completed in accordance with the RAP. During final phases of demolition of the cell room/brine basement structure (in the process building), elemental mercury was found in an area that could not be excavated in the context of current site conditions. To address this area of concern, an assessment of risks to human health and the environment was completed to establish site specific remedial objectives. This report presents the findings of the assessment of these risks.

As an result of the decommissioning activities and the implementation of remedial actions, a Certificate of Compliance has been prepared, under the Nova Scotia Contaminated Sites Management Program, and is included with this report.

2.0 APPROACH AND METHODOLOGY

Site assessment and remedial activities have been ongoing at Canso Chemicals since cessation of chlorine/caustic production in 1992. An overview of these activities is presented in Section 3 of this report. Work completed between 1992 and 1997 has focussed on recovery of mercury and disposal of mercury contaminated materials without demolition of site buildings. Work completed in 1998/1999 has addressed demolition of the process (including cell room and brine basement) and chlorate buildings, and disposal of mercury contaminated materials previously not acceptable due to presence of the building structures. Site materials contaminated with mercury have been disposed in an on-site secure landfill. Section 4 documents groundwater sampling completed by Canso Chemicals Limited as part of its ongoing monitoring program, as well as additional investigations completed specifically for this assessment.

Remedial activities have been implemented to meet the objectives of the 1993 RAP. In June 1999, elemental mercury was identified in the bedrock beneath the area of the former cell room/brine basement. This material could not be excavated in the context of current site conditions (i.e., potential impact on remaining site buildings and potential for increasing the areal extent and depth of mercury impact due to mercury's physical properties). Section 5 of this report presents findings of ecological and human health risk assessments pertaining to the area of the site that has not been remediated to the generic RAP objectives. These risk assessments evaluate potential impacts associated with assumed levels of contaminants. Section 6 presents recommendations for long term monitoring at the site to evaluate the risk assessment assumptions over time.

site rainfall runoff. Mercury was not detected at depths greater than 0.5 metres, but in all cases, the ditches were excavated to a depth of 0.6 metres or more.

By 1996 decommissioning of the facility was essentially complete and the site stabilized for use as an industrial storage space. Little, if any, further remedial work was undertaken until 1998 when the process buildings were removed.

3.2 Remedial Activities 1998-1999

Remedial activities undertaken at Canso Chemicals during 1998 and 1999 have focussed on demolition of site process buildings (the process building and the chlorate building), excavation of remaining mercury contaminated soil (facilitated by removal of building footings) and disposal of mercury contaminated materials in the on-site secure landfill.

The requirements for demolition activities are outlined in the engineering drawings and specifications for the site (Porter Dillon Limited, 1998). Demolition was completed in two phases: building structures were demolished during the fall of 1998. Mercury contaminated debris was stockpiled for disposal in the secure landfill. Other materials were set aside for use as backfill, or disposed off-site. During the spring/early summer of 1999, building foundations and footings were removed and stockpiled for disposal in the on-site landfill. Mercury contaminated soil in the vicinity of the building foundations and footings, which was previously inaccessible, was also excavated for on-site disposal.

Excavation of the mercury contaminated soil was completed to meet the requirements of the 1993 RAP. The RAP objectives were achieved at all locations within the demolition excavation, with the exception of an area in the vicinity of the cell room/brine basement interface. Figure 3-1 presents locations of confirmatory soil sampling undertaken by Porter Dillon upon completion of excavation activities. These samples supplement sampling undertaken by both

5.0 ASSESSMENT OF RISK

5.1 Ecological Risk Assessment

5.1.1 Approach & Methodology

As described in Section 3, elemental mercury has migrated into the bedrock below the former cell room. Due to the practical limitations of excavation, the remedial program was unable to remove mercury below a depth of eight metres. The remaining mercury is located in bedrock, approximately five metres below the water table, and hence there is potential for it to dissolve into groundwater and migrate towards Pictou Harbour.

An ecological risk assessment was carried out to determine whether the mercury remaining in the ground below the former cell room could pose a risk to ecological receptors in the harbour. The assessment was carried out based on procedures described in CCME's Framework for Ecological Risk Assessment at Contaminated Sites (CCME, 1994). The assessment used a preliminary quantitative approach that involved contaminant fate and transport modelling to estimate the potential mercury concentration in the harbour water and sediment. The concentration estimates were compared to CCME Freshwater Aquatic Life Guidelines and Sediment Quality Guidelines for Aquatic Life to determine whether ecological receptors could be at risk.

The ecological risk assessment involved four main components as follows:

- **Receptor Characterization** - evaluation of potential contaminant receptors
- **Exposure Assessment** - evaluation of exposure pathways and exposure concentrations

- **Hazard Assessment** - evaluation of hazards and their possible effects on receptors

- **Risk Characterization** - evaluation of risk based upon the above three inputs

In addition to the above components, a uncertainty analysis was carried out to evaluate the effect of assumptions used in the risk assessment.

5.1.2 Receptor Characterization

A receptor is an ecosystem component that may be adversely affected by a contaminant. Receptors may include biological (e.g., aquatic life) or abiotic (e.g., water quality, sediment quality).

Groundwater flow data presented in Section 4 indicates that the horizontal direction of groundwater flow in the shallow and deep bedrock aquifer is northwest, towards the confluence of the Middle River and West River of Pictou in Pictou Harbour. The data indicate that the vertical direction of groundwater flow at the site is downwards.

There are no water supply wells located down-gradient of the former cell room where the source of mercury is located. The only down-gradient property between the mercury source and the harbour is the Kimberly-Clark paper mill which uses the Middle River of Pictou for process water and bottled water for drinking (pers. comm., Penny MacLeod). Therefore, the receptor of mercury-impacted groundwater is expected to be Pictou Harbour, and the plume is expected to eventually discharge to the harbour approximately 700 m northwest of the former cell room. Both water quality and sediment quality could be affected since dissolved mercury may adsorb to sediments as it discharges through bottom sediments into the harbour.

Aquatic plant life observed by Porter Dillon in July 1999 indicate the harbour can be considered an estuary to marine habitat in the area where the plume may discharge. An electrical conductivity (EC) measurement of the harbour water in this area (EC = 30,000 μS/cm) indicated that the water is in the estuary to marine range (EC = 800 to 55,000 as/cm).

There is also a small pond located adjacent to the harbour in the area where the plume could discharge. The pond is physically separated from the harbour by a causeway, but is hydraulically connected to the harbour by two culverts. Although the pond is a potential receptor of mercury impacted groundwater, is it likely that deep groundwater originating from the Canso Chemical site will bypass the pond and discharge to the harbour further from the shoreline. Shallow groundwater in the vicinity of the pond is more likely to discharge to the pond.

5.1.3 *Exposure Assessment*

Exposure assessment is the estimation of the exposure resulting from the presence of contaminants in air, soil/sediment or water. It often involves contaminant fate and transport modelling to assess the exposure associated with indirect pathways in which contaminants must travel some distance before they reach a receptor.

The data in Section 4 indicate that mercury-impacted groundwater is present down-gradient of the former cell room but the plume has not reached the northern property boundary, located approximately 100 m from the former cell room. Because the impacted groundwater is located at depth, and is not currently discharging to an ecological habitat, there are currently no complete exposure pathways for ecological receptors. However, there is potential for mercury-impacted groundwater to migrate and discharge to Pictou Harbour in the future.

A two-dimensional contaminant fate and transport model was used to predict mercury concentrations that could discharge to the harbour in the future. The

model assumes a constant uniform groundwater flow and accounts for the following contaminant transport features:

- advection (i.e., transport at the speed of groundwater);
- longitudinal and transverse dispersion (i.e., plume spreading), and
- retardation (slowing down of mercury migration due to sorption to aquifer material).

For modelling purposes, the source of mercury contamination below the former Cell Room was approximated as a rectangular mass measuring 18 m wide and 10 m deep. Although the width of the mercury-impacted zone has been measured during the remedial program, the vertical extent is uncertain. The maximum concentration of dissolved mercury in groundwater at the source was assumed to be 60 μg/L. Literature values for the solubility of mercury are in the range of 25 μg/L to 60 μg/L (Environmental Canada, 1984) and the maximum concentration measured in groundwater at the site is 45 μg/L (see Section 4). The mercury source in the bedrock was modelled as a long-term, continuous source that remains at a constant concentration of 60 μg/L (i.e., there is no source decay). Further details about the assumptions and input parameters used in the model are presented in Section 5.1.6 and Appendix E.

The potential concentration of mercury in the harbour was predicted by dividing the maximum predicted mercury concentration in groundwater discharging to the harbour by a dilution factor. The dilution factor was estimated by assuming complete mixing between the plume and the harbour. The flow rate in the harbour available for diluting the plume was estimated from reported flow rates for the Pictou Harbour, East River and Middle River of Pictou. A review of the watershed areas for the East, Middle and West Rivers of Pictou was also carried out. Further details about the assumptions and input parameters used for predicting potential mercury concentrations in harbour water are presented in Section 5.1.6 and Appendix E.

Table 5-1 Summary of Modelling Results	
Parameter	**Predicted Value**
Time for leading edge of Hg plume to reach the harbour (based on a leading edge plume concentration of 0.1 μg/L)	200 years
Maximum Hg concentration in groundwater discharging to harbour (prior to dilution in harbour)	6.3 μg/L
Hg concentration in harbour water (after dilution in harbour)	0.0001 μg/L
Total amount of Hg discharging to harbour	28 grams/year
Hg concentration in harbour sediment	0.0001 mg/kg

5.1.4 Hazard Assessment

A hazard assessment determines the existence of a hazard by investigating the relationship between a contaminant and the receptors exposed to the contaminant.

The fate and transport modelling in Section 5.1.3 indicated that there is potential for mercury to migrate from the site and discharge to the harbour. This may cause aquatic life to be exposed to elevated mercury concentrations in the harbour water and sediment. The main concern regarding elemental mercury in the environment is bacterial conversion to methyl mercury, which is highly toxic to aquatic life, and mercury's ability to bio-accumulate in the food chain. Aquatic organisms may accumulate mercury either directly from water or through the food web. The biological half-life for mercury in fish is approximately two years. Because of rapid uptake and slow cleansing rates, bio-accumulation factors for aquatic organisms are high (approximately 10,000) (CCME, 1987). Table 5-2 presents CCME ecological guidelines for mercury in soil and sediment.

5.1.6 *Uncertainty Analysis*

Risk characterization involves a number of assumptions. In particular, the models used to estimate exposure concentrations in the harbour use a number of simplifying assumptions to facilitate contaminant transport calculations.

A qualitative uncertainty analysis was carried out to assess the degree of uncertainty associated with the modelling assumptions and whether or not the uncertainty was acceptable. The uncertainty analysis evaluated the applicability of the major modelling assumptions and the confidence in key model input parameters. An assessment of whether the assumption could lead to an over-estimate or under-estimate of risk was also carried out.

The results presented in Table 5-4 indicate that exposure concentrations and risks are generally expected to be over-estimated. This is considered acceptable because it is protective of the environment. Some assumptions involving the amount of plume dilution in the harbour may lead to an under-estimation of risk. This is not considered to be an immediate concern because of the length of time estimated for the plume to reach the harbour (200 years) and the very low levels that are predicted to result in the harbour (i.e., three orders of magnitude below guidelines). However, as a precaution, it is recommended that a monitoring program be put in place to confirm the modelling predictions.

5.1.7 *Summary of Ecological Risk Assessment Findings*

The risk assessment indicated that there is potential for mercury-impacted groundwater at the site to migrate and discharge to Pictou Harbour and this could cause ecological receptors to be exposed to elevated mercury concentrations in harbour water and sediment. However, due to slow rate of mercury migration, groundwater plume dispersion, and dilution in the harbour, the mercury is expected to pose negligible risk to ecological receptors.

Attachments:	Alt D 2D modelling results.pdf

20(1)/ Gary,

Attached please find the superimposition of the 2D modelling results for Alternate outfall locations D (500m further and 0.5m deeper than Alt.C) and D2 (1,000m further and 1.0m deeper than Alt.C). Both D and D2 show no backwash of effluent to Boat Harbour while D2 shows no presence of effluent (I'm not calling it an impact…) in traditional lobster fisheries off of Chance Harbour and a minor residual in herring fisheries off of Cole Point and Bay View.

My recommendation would be to proceed with 3-D modelling using the furthest point (D2)

Let me know what you think and when you would be available to have a chat with Stantec on this.

APPENDIX H-4

Introduction

Mandate

1. KSH Consulting was requested to prepare a study benchmarking Canadian effluent discharge permits from chemical pulp mills in order to assess current industrial practices in terms of effluent treatment systems performance and how they compare to proposed new limits facing the Northern Pulp Nova Scotia (NPNS) facility in New Glasgow.
2. The study is required by NPNS for their discussions with government authorities (Nova Scotia Environment) to ascertain if proposed new effluent permits for the mill are comparable and achievable given the age of the mill, technologies employed and the nature of the effluent treatment facilities at NPNS.

Background

3. The Kraft mill located on Abercrombie Point, in the town of New Glasgow NS, has been in operation since 1967. The mill produces bleached (ECF) Kraft market pulp at a current rate of ~300,000 ADt/a. At the time of construction, the Government of Nova Scotia agreed to build and operate a treatment system for the mill's process effluent, which was constructed in the western portion of an area known as Boat Harbour. The system was refurbished in 1996, at which time the mill took over operation of the system. The effluent treatment system consists of constructed sedimentation basins followed by aeration in a natural basin with baffle curtains directing flow. A large, natural final polishing/stabilization basin follows prior to release to the Northumberland Straight.
4. While the system has met federal and provincial standards since 1996, there has been pressure to return some of the natural waterways to their original state and increasingly stringent environmental regulations are being proposed that may require modifications to the system or the effluent streams that feed it to continue operating in the years to come.

Intended for Public Use

Total Suspended Solids (TSS)

1. TSS limits (along with BOD_5) are the longest established pulp and paper emission regulations on the books. From early on, even before organic load mitigation, mills would collect solids coming from their process that were found to be overloading local waterways. Mitigation has ranged from settling ponds to raked clarifiers.
2. As mills have evolved, more and more fibre (the main solid waste) has been retained in the process and sold as product instead of being lost to effluent. This has resulted in a steady reduction in TSS losses.
3. NPNS's proposed TSS daily limit of 4,100 kg/d and monthly limit of 2,460 kg/d equates to approximately 5 and 3 kg/tADt of production respectively, based on 800 ADt/d.
4. As can be seen in the following charts, this would place NPNS as the one of the most tightly restricted emitters of the mills compared for both the daily and monthly limits.
5. NPNS has been able to maintain levels just below this new limit performing at annual average levels of 3.26, 2.61 and 2.05 kg/ADt at Point C for 2011, 2012, and 2013 respectively. In fact, a marked downward trend can be seen.
6. Continued TSS compliance is in fact more difficult for NPNS since there is no final clarifier and lagoons can be prone to rising solids and upsets. Point C of the effluent treatment system also benefits from the settling effect of Boat Harbour prior to Point D, so the impact on marine environments is even less pronounced.
7. Historic data over the past two years has shown 10-15% better performance for TSS losses in the summer. This may be due in part to less solids degradation in the ASB in the winter when temperatures are lower. Seasonal differences in performance (winter to summer) are similar to those reported in the BOD section for NPNS.

Hi,

Port Hawkesbury contacted me after our meeting yesterday. They found an old metal analysis from 2001 and forwarded it to me. I asked 20(1) to add a column in our chart for PHP. Everything in yellow is above the CCME guideline. So basically, they are just the same as us. Neither of us can meet that standard.

Cheers,

Attn: 20(1)
General Manager

Dear 20(1):

RE: Minimum Requirements of a Receiving Water Study

Further to our meeting on June 7, 2017, at your request, the Department offers the following general guidance with respect to the terms of reference for receiving water studies and how they are used to establish end of pipe effluent discharge criteria:

A mixing zone is defined as an area of water contiguous to a point source discharge. A mixing zone is, under no circumstances, to be used as an alternative to reasonable and practical treatment. It must be designed to be as small as possible and it is only one factor to be considered in establishing effluent requirements.

The concept of mixing zones recognizes that the release of the aqueous component of adequately-treated municipal or industrial wastes to watercourses or water resources does occur. As a general principle, the use of mixing zones should be minimized and limited to conventional pollutants. The mixing zone principle does not apply to hazardous wastes or dangerous goods. Mixing zones also do not apply to bio-accumulative or persistence substances and despite the allowance of a mixing zone, effluent shall not be acutely toxic. It should be noted that in this particular case, a receiving water study must address all potential substances of concern not limited to those outlined in the Federal Pulp & Paper Effluent Regulations.

Conditions within a mixing zone must not result in irreversible environmental damage, risk to ecosystem integrity or risk to human health. Mixing zones cannot interfere with other water uses such as drinking water supply, active fisheries or recreation.

As effluent loading requirements are based on careful design, so too should mixing zones be carefully planned on a site-specific basis including consideration of water quality, seasonal streamflow and current patterns, physical factors, biotic communities and spawning areas in and adjacent to the mixing zone, nearby water uses such as public or private beaches and drinking water intakes as well as other wastewater discharges. This information should be provided to the Department.

Intended for Public Use

As general guidance in the design of mixing zones, the following range of concerns should be adequately addressed:

1. In order to protect important aquatic communities (fish, invertebrates and plants) in the vicinity of mixing zones, no conditions within the mixing zone will be permitted which:
    a. are acutely lethal to aquatic life;
    b. cause irreversible responses which could result in detrimental post-exposure effects;
    c. result in bioconcentration of toxic materials which are harmful to the organism or its consumer;
    d. attract organisms to the mixing zones, resulting in a prolonged exposure;
    e. create a barrier to the migration of fish or other aquatic life.
2. To ensure the protection of acceptable aesthetic conditions, mixing zones should not contain:
    a. materials which form objectionable deposits (e.g. scums, oil or floating debris);
    b. substances producing objectionable colour, odour, taste or turbidity;
    c. substances which produce or contribute to the production of objectionable growths of nuisance plants and animals;
    d. substances that render the mixing zone aesthetically unacceptable.
3. Mixing zones should not impinge upon existing municipal and other water supply intakes, public or private beaches or important fish spawning and/or fishing areas. Conversely, new intakes or aquatic recreation areas should not be constructed within the boundaries of existing mixing zones.
4. Mixing zones may overlap unless the combined effects exceed acceptable conditions.
5. When background water quality conditions at a proposed mixing zone site are degraded, effluent discharge requirements established must ensure, at the very least, that background water quality is not further degraded.

The Department requires enough information to ensure each of the above concerns is adequately addressed. Specifically including but not limited to:

- information about the effluent (substances of potential concern, volumes, etc.);
- information about the receiving water (physical characteristics, size, upstream and downstream water quality);
- the location of the receiving water in relation to the facility, the treatment system and the outfall (including a drawing or plan); and
- location of any nearby receptors

With respect to derivation of effluent limits, effluent requirements can be established based on treatment-technology, receiving water concerns, aquatic habitat concerns as well as community concerns including recreational uses. An important factor in the assessment is the use of the principles of assimilative capacity and mixing zone, but it is not the only factor.

The information provided to the Department should include one year's worth of effluent characterization data. For contaminants which are not considered to be designated hazardous

Intended for Public Use

contaminants, every watercourse/water resource has a definable assimilative capacity. Once the assimilative capacity of the receiving water has been determined, end of pipe discharge criteria can be calculated. Water quality considerations take precedence when contaminant discharges exceed the assimilative capacity of the receiving waters, even if the discharged loadings are within the treatment technology based effluent requirements based on the guidelines, regulations or policies. Receiving-water based effluent requirements also take precedence when ambient levels of contaminants are above acceptable levels. Biological effluent requirements may also be specified.

All effluent discharges must not be acutely lethal.

CCME has a guidance document, ***Guidance on the Site-Specific Application of Water Quality Guidelines in Canada: Procedure for Deriving Numerical Water Quality Objectives,*** which you can reference which may be of assistance to you. It can be obtained at the following link: http://ceqg-rcqe.ccme.ca/download/en/221 .

Should you have any questions or concerns regarding this information, please do not hesitate to contact Paul Keats, District Manager at 902-863-7600.

APPENDIX H-7

From: 20(1)
To: 20(1) 20(1) 20(1) Porter, Gary S
Subject: Open houses - ideas for story boards
Date: November 15, 2017 6:57:49 PM
Attachments: image002.png

Hi All,

This is a combination of things that Mike and I have put together as things we should think about addressing through the EA process:

TV screens for 2-D videos. How to present at the meeting?

3 D story board – show effluent plume in relation the background mixing zone and point of outfall for major parameters

EEM summary

History of effluent – existing limits and data over the years (maybe production or maybe express in units/t)

History of effluent – Canso Chemicals, ECF bleaching

History of effluent – how BH came about, legal and historical timelines and possible etc upgrades over the years

Metals in effluent – recent facebook questions (NSE has a piece of this)

Water quality of middle river – not drinking water standards, has color is Michelin effluent. Spills over to harbour if not used.

Effluent parameters – difference from today. Jars made up for color (show historical) and possibly jars made up for TSS. – have several sets of jars made up

Cartoon diagram of AST system – dynamic model showing water going through it.

Aerial maps of areas

Air emissions - difference in odour from existing (septic settling stage, etc), burning of sludge will have to be identified. Possibly get samples of sludge from Port Hawkesbury.

Possibly bring microscope.

History of kraft mills in North America – details of what their systems are.

Ask Domtar is we can use their pictures

Intended for Public Use

Should we bring lobster taste test studies from the 90s?

Where are the moreturium areas for shellfish in the strait?

Background samples of water – GHD ??

No backflow into BH after return to tidal

Show layout – federal water vs provincial water

In mill processes - o2 delig & process water cooling towers (non-contact & water recycle)

Show that fresh water goes over dam and into strait whether or not it goes through the mill or not (out at lighthouse beach). Concern over big fresh water influx.

Michelin effluent is our influent

Fisherman talking about lobster larvae and 30 ft depth that they float and then sink.

Explain toxicity testing – usually means low oxygen & explain how test is done with fish (how to visualize)

Biologist question about adding heat to the strait – RWS less than 1 C (will be higher temp than today however)

Fisherman concerned about stirring up Mercury while we build near the Canso property

Goldboro experience - increase in lobster habitat

Fisherman worried about build up of bottom sludge – specific reference to scallop fishing

Biologist worried about low water circulation in the strait – bottom warming (explain large study area)

Fisherman worried about contamination in BH now and when opened up – mixing up the 2 projects

Worried about oxygen in the effluent – dead zone for fish

Why is new AST better than ASB?

Facebook reference to Paul Klopping Supreme Court appeal letter – odour issues with ASTs too

Bring piece of HDPE outfall pipe – comparison to fiberglass line current

Intended for Public Use

Fisherman concern about difference between PHP and NPNS is that strait of canso is ice fee and Northumberland is not – will effluent get trapped and not flow? How does ice cover affect outfall?

20(1) – right now mill has BH as large buffer zone, so effluent at point C is not comparable to new effluent. Need to compare to Point D or speak to difference between current point C and D.

20(1) - Why not closed loop system? Offering up a cheap solution, not a good solution

20(1) has 2012 KSH study that says AST quality not significantly different than ASB

20(1) – all toxic sludge will now be burned in the PB and end up as air emissions.

Excellence… It is in our name, our vision, and our values

Since its inaugural year in 2010, Paper Excellence Canada (PEC) has evolved from a new entrant as an exporter to a leader in Canada's value-added natural resources (pulp) industry. Achieving sales in excess of $1 billion through its seven Canadian mills, PEC has accomplished this level of sales volume through innovation and best practices in all areas with a commitment to deliver premium quality products to all customers. Through its Richmond-based headquarters which hosts an employee base of 100 supporting over 2300 employees in Canada and Europe, PEC continues to lead by example operating through economic and environmentally sustainable best practices.

Hi 20(1)
See updated responses to your additional questions below
20(1)

Thanks for getting back to me. I do have a few more questions.

1. Would the new facility fall under the current lease with the province?

The facility will be built on the mill site.

2. When would you expect a formal application to be made to the province for the plans?
Dillon Consulting has been hired to assist in the Environmental Assessment (EA) process. There is much work to be completed before the application can be filed. One of the first steps will be public consultations.

3. There are a lot of concerned fishermen that are worried about how this new treatment facility will affect the water in the Northumberland Strait. Are they right to be concerned?
Treated effluent has been flowing through Boat Harbour and into the Northumberland Strait for over 50 years. The new treatment facility and diffused outfall will reduce the impact on the Strait. For example, the new outfall is designed to meet the Canadian Council of Ministers of the Environment (CCME) guidelines for effluent discharges which stipulate that all effluent parameters of concern should meet background concentrations of the receiving water in less than 100 metres from the outfall.

4. If the plans are rejected by the province, what is the next step for the company?
We are working cooperatively with the Government of Nova Scotia to design a treatment facility that meets all environmental requirements.

Hello 20(1)

Thank you for your email. Please see below bulleted information answering your query. Please feel free to email me if you have further specific questions and deadline you are working with. I am in meetings for the remainder of the day but will be able to access email periodically.

You may attribute the response to 20(1) Director of Communications, Paper Excellence
Kindly
20(1)

-KSH Solutions Inc has recently completed preliminary engineering where all available technologies were reviewed. Activated Sludge Treatment (AST) was recommended as the best and most reliable process for treatment for the new facility to be located on existing mill property.

-The proposed new treatment system will be a modern AST system that mills and other facilities (industrial, municipal, etcetera) throughout the world have in place.

-The current effluent treatment system is an ASB system. In North American Kraft mills, there are predominantly two systems used to biologically treat industrial wastewater, the aerated stabilization basin (ASB or aerated lagoon) and the activated sludge system (AST). These two systems have far more similarities than differences. Both processes are based on the utilization of dissolved oxygen by microorganisms in converting organic and inorganic matter into a settleable form. The ASB process uses a large aerated lagoon and long retention times (days) whilst the AST process treats the wastewater in hours and involves two stages – an aeration stage and a clarification and recycle stage. AST systems generally operate at higher removal efficiencies as compared to ASB systems.

-In early October, Dillon Consulting of Halifax was contracted to provide professional guidance throughout the entire Environmental Assessment process, including creation of the Environmental Impact Assessment (EIA) project registration document.

-Presentation of all scientific information as well as documentation of public and stakeholder concerns, complete with how they will be addressed, are an important and vital part of the consultation process and EIA document.

-The effluent pipeline (outfall) will be designed with an engineered diffuser which is also an improvement from the current system.

-The new outfall is designed to meet the Canadian Council of Ministers of the Environment (CCME) guidelines for effluent discharges which stipulate that all effluent parameters of concern should meet background concentrations of the receiving water in less than 100 metres from the outfall.

-Construction would begin upon registration and approval of the project by Nova Scotia Environment.

Northern Pulp's plans for pipeline, effluent treatment plant now public

Environment minister has until March 29 to decide whether plan is acceptable

Jean Laroche · CBC News · Posted: Feb 07, 2019 1:15 PM AT | Last Updated: February 7

Northern Pulp has released details of its plan to build a new effluent treatment plant and discharge pipe. (Jeorge Sadi/CBC)

Nova Scotians now have access to the details of Northern Pulp's controversial plan to build a new effluent treatment plant and discharge pipeline that will empty into the Northumberland Strait.

The Pictou County pulp mill's 614-page document, including 18 appendices, was filed with Nova Scotia's Environment Department a week ago and was posted Thursday on the

department's website.

The plan put forward to the Environment Department is to build a "biological activated sludge" treatment facility purchased from a Paris-based multinational corporation called Veolia Water Technologies.

The corporate website says Veolia Water "specializes in water treatment solutions and provides the complete range of services required to design, build, maintain and upgrade water and wastewater treatment facilities for industrial clients and public authorities."

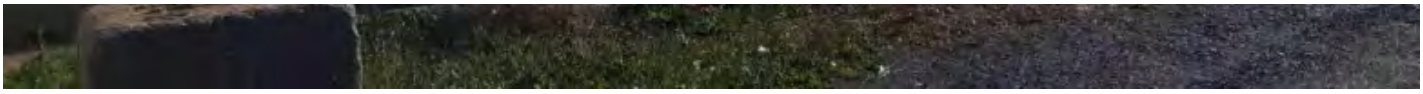
Nova Scotia Environment Minister Margaret Miller said the nearly 2,000-page submission was not a surprise.

"I think it's pretty much what the department was expecting," she said.

Safe drinking water a concern

The treatment facility would be located on Northern Pulp property not far from the existing plant.

The 15.5-kilometre pipeline would run from the new facility along the shoulder of Highway 106 to Caribou before entering Caribou harbour next to the Northumberland Ferries terminal. From there, it would discharge roughly four kilometres into the Northumberland Strait.



A boat doing survey work for the proposed Northern Pulp effluent pipe is tied to the wharf in Pictou, N.S. (Submitted by Ben Anderson)

That route is a concern for the town of Pictou. Mayor Jim Ryan said it means wastewater will be piped over the town's main watershed.

"This particular issue is about safe drinking water," he said in a telephone interview Thursday.

Ryan said he told Northern Pulp general manager Bruce Chapman in November that any plans for a pipe that carries treated or untreated effluent through the watershed would be unacceptable to the town.

Work would take 21 months

Northern Pulp's plan to discharge treated effluent into the strait has also been controversial.

Thousands protested last July over concerns it would hurt the environment. Fishermen had also prevented a survey crew from doing work for the company, but agreed last month to a court injunction ordering them not interfere.

Northern Pulp protesters outside a Supreme Court injunction hearing late last year. (Preston Mulligan/CBC)

Company owners have also sought a one-year extension of the provincial law requiring the mill's current treatment facility in Boat Harbour to close in January 2020. The company has argued it needs more time to build a replacement, but Premier Stephen McNeil has refused to extend the deadline.

According to company documents, the plan is to complete the work within 21 months, starting this spring. That means a working system would not be in place until 11 months — at the earliest — after the provincial government is legally mandated to turn off the tap to the provincially owned treatment plant.

Pipe would mostly be buried

The company has proposed using a polyethylene pipe that's 90 centimetres in diameter to carry the treated effluent from the plant to the dispersal site.

"The terminus of the effluent pipe consists of an outfall location with the three-port diffuser, situated at the depth of approximately 20 [metres]," says the project description.

The plan is to bury the pipe along most of the route, but the company is proposing suspending it to the exterior of the bridge that crosses the Pictou Causeway "due to the limited roadway width."

"The exposed area will be protected from damage by existing guard rails," says the document.

Northern Pulp's proposed route for the effluent pipe would go from a new treatment plant into the Northumberland Strait. (Nic Meloney/CBC)

The company has promised to mark the pipeline location with signs and post markings at public and private roads and water crossings. The system will also need a pumping station which the company states "will operate in a similar manner to municipal pumping station."

Serious impact on lobster 'highly unlikely'

The company said it looked at alternatives to the plan it has submitted for provincial approval, including simply shutting down or creating a closed wastewater recovery system, but none was feasible.

An indication of how much the company wants an extension is the people it has hired to lobby the governing Liberals on its behalf: Kirby McVicar, McNeil's former chief of staff; Stephen Moore, McNeil's former director of communications; and Trevor Floyd, a one-time executive assistant to Health Minister Randy Delorey when he held the environment portfolio.

- **Premier unmoved by Northern Pulp's ask for more time to close waste water facility**

As for concerns expressed by opponents to the plan, the company has included a response to 38 questions or comments, ranging from the possible harm to lobster stocks to heavy metal

contamination and the environmental review process.

The company stated "it is highly unlikely that there will be serious impact on lobster," and that heavy metals occurred naturally in the environment "and are released to the environment from a range of human and natural sources."

Public invited to submit comments

As for the review process, Northern Pulp noted it was a provincial process but the Canadian Environmental Assessment Agency would review the company's application to determine whether a federal environmental assessment was necessary.

Nova Scotia Environment Minister Margaret Miller has until March 29 to make a decision on Northern Pulp's plan. (CBC)

The public now has until March 9 to digest the information and submit their comments, either by mail or using an online form.

Miller has until March 29 to decide if the project will be granted conditional environmental assessment approval. Officials in her department will sift through the material to ensure it provides a complete picture of the plan and its potential impact on the environment.

If additional work is needed, they can ask the company to provide it. But Miller said the consultation period would not be extended beyond the 30 days if that were to happen.

She acknowledged the existing file could be a challenge for Nova Scotians to assess.

"I don't know that the public is really going to be able to fully digest everything that's been submitted."

Excellence… It is in our name, our vision, and our values

Since its inaugural year in 2010, Paper Excellence Canada (PEC) has evolved from a new entrant as an exporter to a leader in Canada's value-added natural resources (pulp) industry. Achieving sales in excess of $1 billion through its seven Canadian mills, PEC has accomplished this level of sales volume through innovation and best practices in all areas with a commitment to deliver premium quality products to all customers. Through its Richmond-based headquarters which hosts an employee base of 100 supporting over 2300 employees in Canada and Europe, PEC continues to lead by example operating through economic and environmentally sustainable best practices.

Hi 20(1)

Here's what I was able to put together, based on the comments in your e-mail. It's all under the same file (the zero-effluent file I sent yesterday), which is dated today and is in PowerPoint format (easier to extract)

I included some additional info that could be useful to others as well.

Let me know if you need anything else

Subject: Mill proposed slides - story we need to tell

This is the story I think we need to tell:

Simplified description of EA process – Class I and II (show timeline schematic on handouts that ends in June/July 2018, make a second schematic that starts at Registration and ends at decision and show steps or milestones, point out that other agencies involved (DNR, DFO, trans, ECCC) not just NSE. (Dillon)

What is effluent? Why treat it? What is in it? (20(1)

Map of existing ETC – point out pipeline, current process equipment and dam and outfall to Pictou Road (Dillon)

Water supply to the mill – aerial picture (attached) – will explain 3 rivers running to harbour, Michelin and NPNS water supply, unused water spills over dam, RV Anderson report on sustainability (incredible # of people worried we are going to dilute the Strait with fresh water – they need to know it goes there anyway) – (Dillon to identify 3 rivers, dam, pumping station, causeway underflow, Michelin, NPNS and existing and new outfall on the map) (mill– sample bottle and talking points)

- Sample bottle of color, doesn't meet CCME drinking water standards.

Options considered – how did we pick AST? BAETA methodology. Why not zero effluent, table (summary) of North American systems who has ASB, AST and marine or FW discharges? no mills in NA running anything else. Speak to Europe and asia . Closed loop build up of chloride in our boilers, corrosion control – cathodic protection on your boats. (20(1) to provide)

In mill changes to support ETF – O2 delig and cooling tower slide (and picture of CT) – run seasonally only to reduce summer cooling water flow, RWS did not consider O2 delig improved quality, not sure of start-up and commissioning times, ETC more conservatively designed for extra aeration. Cooling towers use more fresh water due to evaporation. Water and effluent flows not equal. (20(1) – moved after why we picked AST, improvement to support new AST)

New system – 3 pics - block diagram (20(1) aerial layout and pipeline aerial layout (Dillon 2 aerials) – point out that old pipeline was untreated and new pipeline is after treatment.

Differences between AST and ASB – why better process. more modern, confidence in best system. 20(1))

RWS - 30 day lunar cycle July 2016 – most challenging month for river inflow (conservative case) – show map of study area from stantec report. High effluent loading for 30 days straight with no biological degredation. (Dillon)

Why outfall selected where it was? Locations considered in RWS – both inside and outside harbour

Intended for Public Use

Inside harbour could lead to build up of nutrients (nitrogen and phosphorous) – eutrophication. Had to be far enough from entrance to BH to ensure no eutrophication there either. (Dillon)

Design of line – marine geotech, ROV to confirm path not impacting sensitive habitat or marine protected areas. Picture or sample of HDPE pipeline for thickness. Rock mattress, diameter of line, 1 m estimated armour stone cover, create habitat. Why we show a corridor, not a line. Questions about top of line being hazard to navigation – someone said 9 ft minimum at entrance to harbour at low tide – check. Show we are OK? (Dillon)

Design of the diffuser – pictures of diffuser (schematic and photograph - attached), (Dillon)

6 ports chosen – modelled 1, 3 and 6

Meet guidelines for CCME – table of parameters and distances (include 20(1) note on salinity)

Aerial showing mixing zone

stantec sensitivity maps considered – show?

History of Effluent Quality – time/project/impact/effluent sample bottles. Last line will be predictions for the project (NPNS to provide mark up, Dillon to draw up) including 1992 and 1997 changes. Possibly by increments of decades. How do we explain difference between in and out of BH? ASB data from 2009 to present is into BH, data before 2009 is out of BH. Some say effluent quality will be worse than today because of all the polishing that is happening across the BH basin – and they are correct to some extent.

Summary of EEMs – chart of year/study/result (not sure if this is a good idea or not?) 20(1)

Effluent temperature – hotter than now (BH big basin provides a lot of natural cooling today). Give temperatures and explain CCME meeting 1C guideline (0.2 or 0.3 in 100 m this is in July when ocean the warmest. 3 dimensional plume. Mixing zone above the benthic layer. Add Table from Stantec report showing 0.2 C increase. (Dillon)

Solids – concern about large amount of solids (greater than 1000 kg/d). GUY – what percentage of solids is organic or bug bodies? Compare future to current – speak of high solids in history (especially pre 1990s). One of lower mills in Canada. Concern over build-up of bottom sludge and scallop fishing. 20(1) – will we speak to odour m??

Metals/Dioxans and Furans – don't know what to do with this. How to handle questions around burning of sludge that all other mills do? Are municipal ETC's burning sludge? (Dillon) metals from wood – also burned in wood stoves.

List EA studies completed, ongoing and planned. (Dillon)

Like the "anticipated change chart" in LaFarge Cement EA also Irving EA – could we make same? Include positive and negative and things that stay the same – odour, sludge burn vs landfill, color

Intended for Public Use

and organic improvements, solids about same, rock cover, energy reduction, less CO2 emissions, economic, etc. – work on this together on Friday

Four studies to share: Timeframe?

1. RV Anderson – Middle River Sustainability
2. KSH Phase I
3. KSH Phase II ??
4. Stantec RWS

To add to frequently asked questions:

Is dilution the solution to pollution for Northern Pulp? Industry standard limits as well as current PPER limits are mass-based (ex. kg/day) and not based on volume. Therefore adding more fresh water to the effluent does not make effluent limits easier to meet. The RWS was conducted at design flow. Reducing effluent flow results in an improvement in meeting CCME guidelines compare to the higher design flow. Therefore, there is no benefit to adding dilution to the effluent.

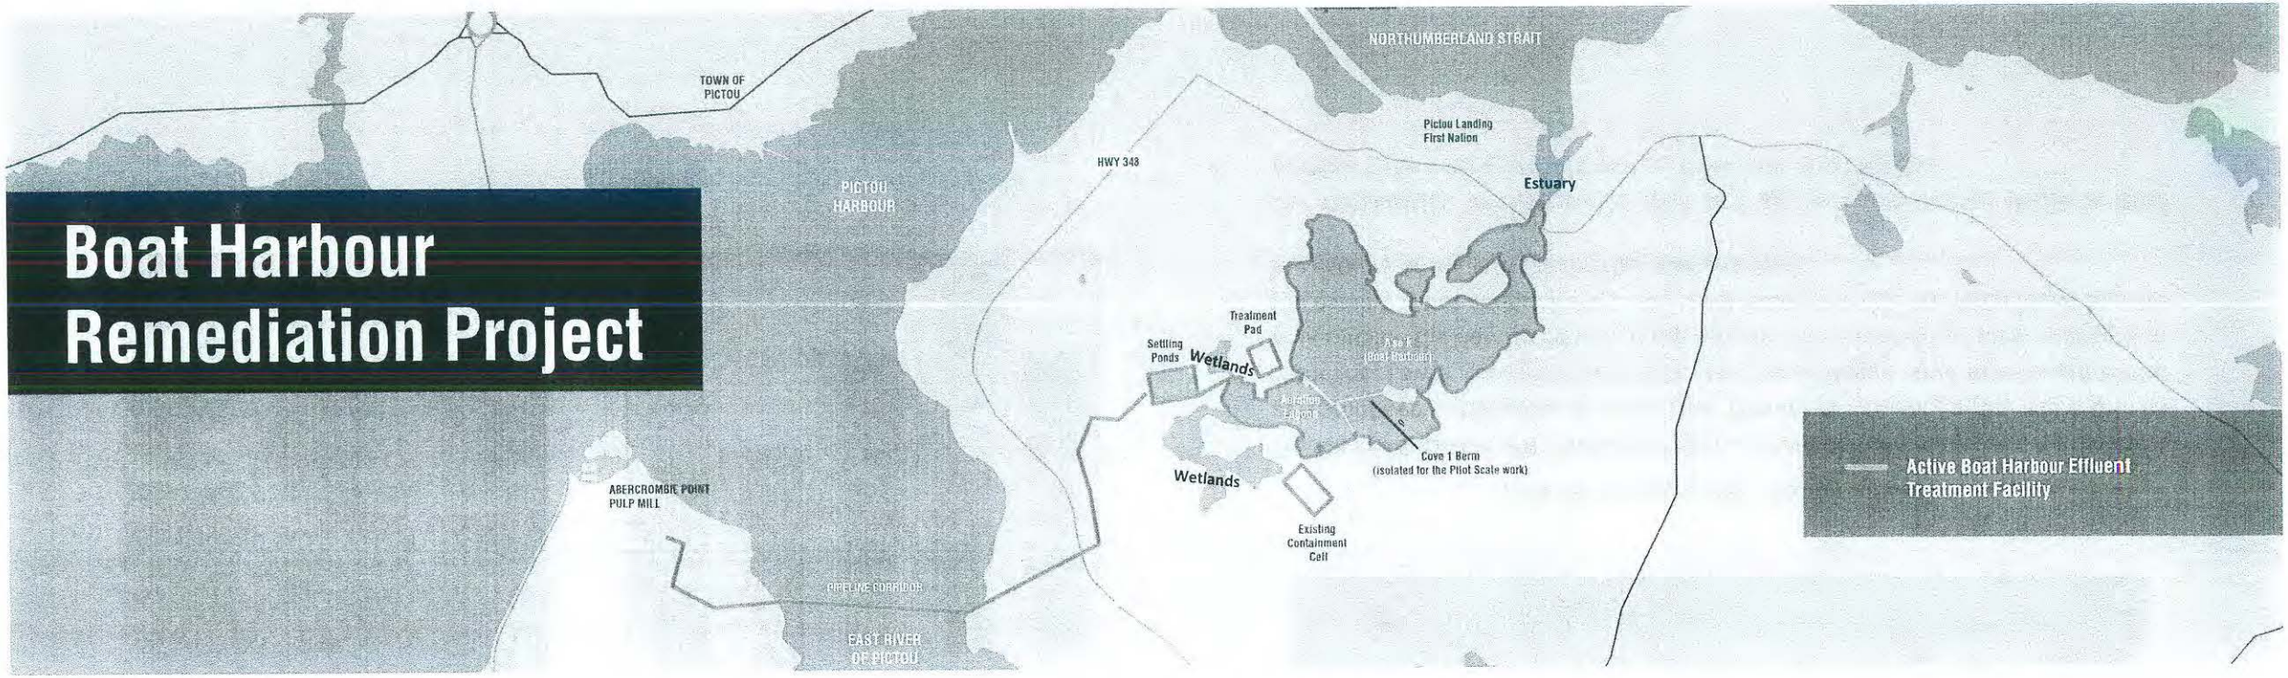
APPENDIX H-11

Boat Harbour Remediation Project



Boat Harbour Sludge – Our Problem

What contaminants are in Boat Harbour?

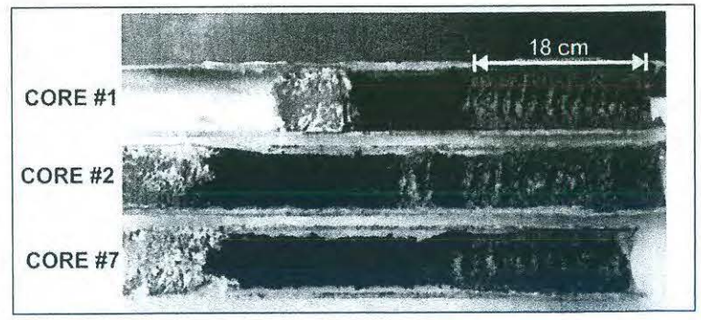
A layer of contaminated sludge has settled on top of the Boat Harbour bottom. This sludge has been accumulating since 1967. It has been sampled many times over the years. A full suite of testing was completed in 2017 which has confirmed the contaminants in the sludge. Over time, the contaminants have not changed.

We know the sludge contains:

- Dioxins and furans, the principal contaminants of concern are carcinogens which are residues of industrial processes
- Metals such as mercury, cadmium and zinc, which are residues of industrial processes
- Polycyclic aromatic hydrocarbons (PAHs), which can be produced by incomplete combustion of fossil fuels in engines and boilers or from forest fires
- Total petroleum hydrocarbons (TPH), a term used for any mixture of hydrocarbons that are found in crude oil and petroleum products
- Volatile organic compounds (VOCs), include human made residues from industrial processes and naturally occurring chemical compounds.

The contaminated sludge is generally less than a foot, or 30 centimeters, thick and is black in colour while the underlying marine sediment is brownish gray and is not contaminated.

The wetlands above Boat Harbour have also been impacted from the early years of Mill operations and contains contaminated sediments.



This image shows several core samples taken from Boat Harbour, the black contaminated sludge is clearly visible; the brownish gray is the clean Pre-industrial marine sediment and, the bentonite is a clay product put in the core during sampling as a plug - **Note:** The figure shows from left to right bentonite plug, black contaminated sludge, brownish gray pre-industrial marine sediment

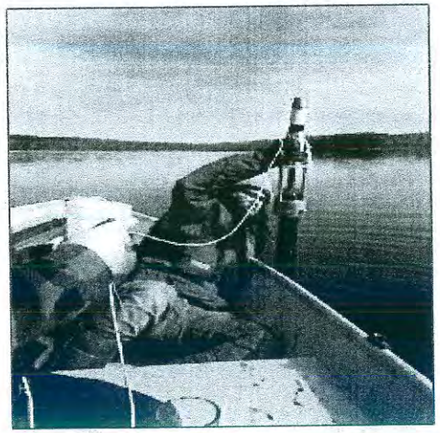
Boat Harbour Remediation Project

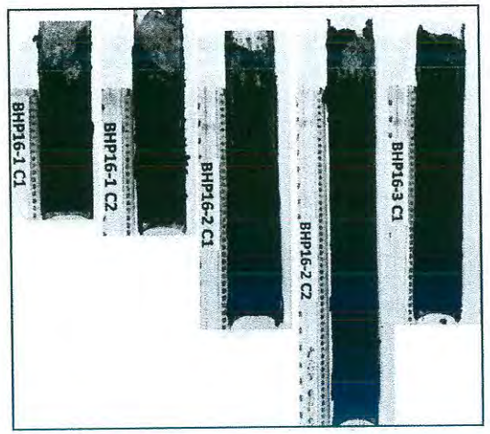
How much is there?

The contaminated sludge in Boat Harbour is of a soft, wet nature and is unevenly distributed along the harbour bottom. We have estimated the volume of material to be removed from Boat Harbour to be as much as 1,000,000 cubic meters. This number includes some of the marine sediment on the harbour bottom that will accompany removal of the contaminated sludge. To effectively remove the contaminated sludge, we need to take some of the marine sediment. Once the material is removed it will be treated, dewatered and its volume will be significantly reduced to about 500,000 cubic meters.

Sampling procedure

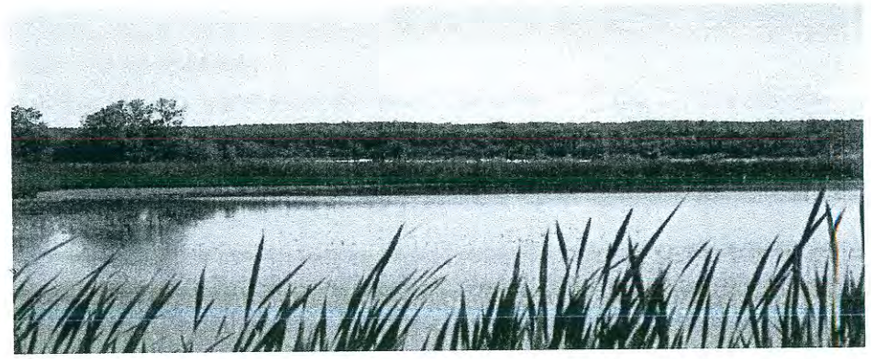
All sampling followed scientific protocols based upon generally accepted procedures. These protocols were vetted with Dr. Ian Spooner, a geoscientist and sampling expert from Acadia University.





The wetlands

Twenty-five wetland areas are around Boat Harbour and are identified as marsh and/or swamp complexes. One wetland of about 36 hectares in area, pictured below, is situated near the existing settling ponds and was impacted by early years of effluent discharge. The remediation planning is considering either removal of all the impacted sediments or a risk-based approach which may involve removal of areas of higher contamination and allowing monitoring and natural attenuation (treatment) for the balance of the wetland.



How far has the contamination spread?

Studies conducted in 2017 show that the contaminated sediments are, for the most part, confined to the active Boat Harbour Effluent Treatment Facility and within its shoreline. Lower concentrations of contaminated sludge have been found in the area outside the dam structure, in the estuary. The underlying marine sediment in the estuary is not contaminated. No contaminated sludge has been found beyond the estuary or out into the Northumberland Strait.

Our remediation will ensure we deal with all the contaminated sludge in Boat Harbour before we allow tidal waters to re-enter Boat Harbour.

APPENDIX H-12

Chapter 4: Environment – Environmental Assessments

Overall Conclusion:

- Poor monitoring of projects increases risks to the environment
- Monitoring of terms and conditions of project approvals is weak
- Department not evaluating whether terms and conditions are working
- Department meeting legislative requirements for issuing approvals

Why we did this audit:

- Protecting the environment is important to Nova Scotians
- Environmental impacts should be known before a project begins
- Steps should be taken to limit environmental impacts of projects
- Projects should be monitored to ensure the environment is protected

What we found in our audit:

Monitoring of approved projects

- Monitoring not done for almost half the project terms and conditions we tested
- Department not appropriately recording all approved projects in tracking system
- Department hasn't assessed if terms and conditions have decreased environmental risks
- Department taking steps to improve monitoring

Setting terms and conditions for project approval

- Some terms and conditions lack details such as deadlines and reporting requirements
- Approvals issued without consulting inspectors who know risks
- Lack of discussion with project owners on understanding terms and conditions
- Department doesn't follow up with project reviewers to ensure responses provided

Approving project applications

- Applications for approvals contained information required by legislation
- Minister given all required information to make project approval decision
- Terms and conditions of approvals can reduce risks, but are less useful because of poor monitoring

Recommendations at a Glance

Recommendation 4.1
Environment should develop and implement a process for entering approved projects and the associated terms and conditions into the Department's tracking system to help ensure regular monitoring is completed.

Recommendation 4.2
Environment should regularly review whether standard terms and conditions of approved projects are effective at addressing identified risks.

Recommendation 4.3
Environment should develop terms and conditions for approved projects in consultation with the inspectors responsible for ensuring they are met. Terms and conditions should include clear timeframes for completion and requirements to provide documentation to confirm terms and conditions have been satisfied.

Recommendation 4.4
Environment should provide relevant draft terms and conditions of approved projects that involve other departments to the respective departments for review and confirmation of their responsibility under the terms and conditions.

Recommendation 4.5
Environment should meet with project owners to discuss the terms and conditions once projects are approved. There should also be regular meetings between Nova Scotia Environment and project owners to discuss the status of terms and conditions of approved projects.

Recommendation 4.6
Environment should document and implement a process for using government reviewers on environmental assessment applications. The process should include how reviewers are selected, the Department's expectations of reviewers and a follow-up process if responses are not provided by the deadline.

Recommendation 4.7
Environment should complete and document a review of information sent to the Minister of Environment for deciding on whether to approve or reject a project.

4 Environment: Environmental Assessments

Background

4.1 Nova Scotia Environment uses environmental assessments to identify potential negative environmental impacts of proposed projects before they begin. The goal is to approve sustainable projects while also promoting the protection and appropriate use of the environment. The Minister of Environment decides whether a project can proceed if the results of the assessment determine the potential impacts can be properly managed.

4.2 An environmental assessment is not required for every proposed project. In Nova Scotia, the Environmental Assessment Regulations list the types of projects that require an environmental assessment. Projects requiring an environmental assessment can include wind farms, quarries, pipelines and energy facilities. From 2013 to 2016, 53 of 54 environmental assessments conducted were approved.

4.3 Terms and conditions that project owners must meet are attached to project approvals. The purpose of these is to address environmental risks identified through the assessment process and ensure steps are taken to reduce the impact of the project on the environment. A typical approval includes approximately 30 terms and conditions such as monitoring programs for wildlife, habitat and groundwater well surveys. Nova Scotia Environment is responsible for ensuring project owners are complying with the terms and conditions of the approval and determining whether risks to the environment are being reduced.

4.4 An environmental assessment approval allows a project owner to proceed with the proposed project. However, projects may not immediately start when the approval is received and for some types of projects, additional approvals, such as industrial approval or wetland approval issued by Nova Scotia Environment, are needed before the project can begin.

Significant Audit Observations

Monitoring of Environmental Assessment Approvals

Terms and conditions are not monitored

4.5 Nova Scotia Environment is not monitoring terms and conditions attached to approved projects. Terms and conditions are future actions added to

approved projects to address risks projects pose to the environment. These can include various wildlife and habit monitoring programs, or restricting construction during animal breeding seasons. Failure to properly monitor compliance with these requirements increases the risk that project owners are not protecting the environment. Without monitoring, Nova Scotia Environment does not know if the terms and conditions of approved projects are effective in reducing impacts on the environment.

4.6 We reviewed a sample of 22 approved projects which contained 672 terms and conditions. We then selected two to three terms and conditions from each approved project to determine if Nova Scotia Environment had evidence to confirm the term and condition had been satisfied. In total, we examined 53 of the 672 terms and conditions identified. For 23, the Department did not confirm the term and condition had been satisfied. For example, Nova Scotia Environment did not have evidence to confirm requirements such as groundwater well and wildlife surveys were completed by the project owner or work was completed outside of animal breeding seasons.

List of approved projects and terms and conditions not complete

4.7 Nova Scotia Environment did not record approved projects and their associated terms and conditions in its electronic tracking system. This meant inspectors were not assigned responsibility for monitoring terms and conditions of approved projects and were unable to take advantage of system features that help in monitoring. Features include reminders of when inspections and audits are due, and allows managers to monitor the work of inspectors.

4.8 Management uses the information included in the tracking system to ensure the required monitoring is completed. If approved projects are not in the tracking system, managers do not have access to complete information and may not know if terms and conditions are properly monitored.

4.9 Other approvals, such as industrial and wetland approvals issued by the Department, are automatically loaded into the Department's tracking system and assigned to an inspector. One division within Nova Scotia Environment is responsible for approving projects while another division oversees whether project owners are satisfying the terms and conditions of approved projects. Once the approval is issued, it must be manually entered by the division responsible for monitoring project owners for compliance with the terms and conditions. However, this did not happen.

4.10 Nova Scotia Environment conducted an internal review in 2015, finding that only 75 of the 276 environmental assessment approvals issued between 1989 and 2015 had been recorded in the tracking system. They also concluded for almost all the approved projects entered in the tracking system, the terms and conditions of the approval were not included. Until the Department identified

this issue there was nearly no monitoring of the terms and conditions attached to approved projects.

4.11 Nova Scotia Environment has worked to address these issues, but our work found that there are still problems. Four of the 22 approved projects we examined were not recorded in the tracking system. For 15 of the remaining 18 approvals, the terms and conditions were not added to the tracking system in a way which allowed the inspectors to use the system features for monitoring.

4.12 Information on terms and conditions was not stored in a single file for each approved project, making it difficult to confirm if terms and conditions had been met. When completing our work, we often had to look in several different locations to determine if terms and conditions had been satisfied.

4.13 For example, we identified several cases in which the project owner provided requirements such as wildlife surveys and confirmation of site restoration insurance to staff at Nova Scotia Environment or other government departments, but it was not passed on to the inspectors responsible for monitoring the approval. Inspectors did not know the information was provided nor did they follow up with the project owners to request the information.

4.14 All information related to the terms and conditions of approved projects should be kept in a central location so it can be quickly determined which ones have been satisfied and those that still require monitoring.

Recommendation 4.1
Environment should develop and implement a process for entering approved projects and the associated terms and conditions into the Department's tracking system to help ensure regular monitoring is completed.

Environment Response: *Agree. In February 2017, NSE implemented a System of Notification and Approval Processing (SNAP). Going forward, approvals will be captured in the system to enable terms and conditions to be tracked. Timing: Currently underway*

Regular assessments of terms and conditions not completed

4.15 Neither the Department nor project owners completed the required assessments for any of the projects we examined. Without this reporting, Nova Scotia Environment does not have the necessary information to ensure terms and conditions of approved projects were satisfied and environmental risks were properly managed.

4.16 Nova Scotia Environment's documented process for monitoring the terms and conditions of approved projects includes:

- a Department assessment of whether terms and conditions are met and effective at reducing risk; and
- a review of the project owner's assessment of whether terms and conditions are met along with comments or suggestions for future environmental assessments.

4.17 Nova Scotia Environment's evaluation of the effectiveness of the terms and conditions of approved projects for reducing risks to the environment is especially important. This evaluation considers things such as the results of water or wildlife monitoring completed by the project owner, results of Departmental inspections, and complaints received against the project. Without this information, the Department may not be aware of the need for additional monitoring or changes to the terms and conditions. This process also provides information that can be used by the Department when approving future projects.

4.18 Nova Scotia Environment staff acknowledged this process is not followed and noted it needs to be updated since it was developed and implemented in 2002. While we recognize the process is old and there have been changes within the Department since 2002, regularly assessing the status and effectiveness of the terms and conditions of approved projects is an important practice that should be completed.

Recommendation 4.2
Environment should regularly review whether standard terms and conditions of approved projects are effective at addressing identified risks.

Environment Response: *Agree. We have committed to reviewing and updating the Internal Guide to EA Follow-up Procedures. This guide will establish procedures for reviewing Environmental Assessment terms and conditions to ensure enforceability leading to better compliance. Timing: 2017-18*

Approval of Projects

Wording of terms and conditions attached to approvals not clear

4.19 Applications are reviewed by Nova Scotia Environment to identify risks to the environment posed by the project. Approvals are subject to owners satisfying the terms and conditions included with it. If terms and conditions are not properly developed it is possible risks to the environment may go unaddressed.

4.20 The terms and conditions attached to approved projects were not always clear and well defined. We found problems with 11 of the 53 terms and conditions we examined. Specific issues included no established timelines for when the project owner must comply, no requirement to submit documentation to confirm a term and condition has been satisfied, and no indication of who the supporting documentation must be submitted to.

4.21 For example, one term and condition stated *"The Approval Holder must develop a turbine lighting plan in consultation with CWS [Canadian Wildlife Services] and Transport Canada"*. There was no deadline for the development of the plan and no requirement for the plan to be submitted to Nova Scotia Environment. The Department did not know this was completed until we asked about it as part of the audit.

4.22 Nova Scotia Environment's ability to hold project owners accountable is limited when terms and conditions of approved projects are not clear. This increases risk to the environment. For example, if a project owner is not required to provide documentation to confirm a term and condition has been satisfied, it is difficult for the Department to act against the project owner if nothing is submitted. Inspectors told us they had concerns related to the enforceability of some terms and conditions. Inspectors believed their lack of involvement in the development of the terms and conditions contributed to this issue.

4.23 The Department's process states draft terms and conditions are to be given to inspectors for review and feedback before final approval. However, based on our work, this did not always happen. For 11 of the 22 approved projects we examined, the terms and conditions were not given to inspectors for review before the approval was issued. Inspector input on terms and conditions is an important step in setting clear and enforceable expectations for project owners and limiting impacts on the environment.

Recommendation 4.3
Environment should develop terms and conditions for approved projects in consultation with the inspectors responsible for ensuring they are met. Terms and conditions should include clear timeframes for completion and requirements to provide documentation to confirm terms and conditions have been satisfied.

Environment Response: *Agree. NSE is undertaking a larger project to review terms and conditions of its approvals including EA authorizations. The project is intended to update/review existing terms and conditions to ensure requirements are relevant, clear, consistent and enforceable. Timing: 2018-19*

Responsibility for some terms and conditions not established

4.24 Nova Scotia Environment did not review terms and conditions of approved projects with other departments before approval. Departments other than Nova Scotia Environment are often responsible for receiving information from project owners and confirming if terms and conditions have been satisfied. However, Nova Scotia Environment did not consult with other departments on the terms and conditions before issuing the approval. For example, the project owner might have to develop a moose monitoring program that is to the satisfaction of the Department of Natural Resources. If Nova Scotia Environment does not discuss terms and conditions assigned to other departments with those departments, those other departments may not be aware of their responsibility or understand of what is expected of them. This could result in terms and conditions not being properly monitored or information not passed on to Nova Scotia Environment.

Recommendation 4.4
Environment should provide relevant draft terms and conditions of approved projects that involve other departments to the respective departments for review and confirmation of their responsibility under the terms and conditions.

Environment Response: *Agree. The review and update of the EA Checklists will ensure a record of communication with other departments is clear and a record is maintained. Timing: June 2017*

Review of terms and conditions with project owners not done

4.25 The Department did not review terms and conditions of approved projects with the project owners as required. These meetings help ensure project owners fully understand what is required of them and the expectations of Nova Scotia Environment. For example, meetings can provide an opportunity to discuss periods during the year when project owners are not allowed to clear land or steps that must be taken to monitor wildlife within the project area.

4.26 The Department's process is to meet with the project owner within four weeks of the project being approved to review the terms and conditions. This meeting did not occur for three of the 22 approved projects we examined. For another seven projects, the meeting was not held within four weeks of the approval being granted. In two of these, approximately a year had passed before Nova Scotia Environment met with the project owner.

Recommendation 4.5
Environment should meet with project owners to discuss the terms and conditions once projects are approved. There should also be regular meetings between Nova Scotia Environment and project owners to discuss the status of terms and conditions of approved projects.

Environment Response: *Agree. The Internal Guide to EA Follow-up Procedures will be updated to ensure the initial meeting with the approval holder is completed. Subsequent meetings with the approval holder to review terms and conditions will be captured during an audit or inspection process. Timing: 2017-18*

Better processes needed for reviewers of environmental assessment applications

4.27 Government reviewers were used to assess each of the 22 approved projects we examined. As an example, applications were sent to divisions within Nova Scotia Environment to assess a proposed project's impact on groundwater, while the Department of Natural Resources was used to identify risks to wildlife. Comments from reviewers were considered in developing terms and conditions for approved projects.

4.28 While the use of reviewers provides valuable feedback on proposed projects, improvements are needed. Currently, applications are sent to a broad list of reviewers. For some of the environmental assessment applications we examined, the documentation was provided to over 40 individuals. The Department does not have a process to identify the specific reviewers that should be used. Furthermore, no guidance is provided to reviewers on what Nova Scotia Environment's expectations are for the review. For example, it isn't clear whether the individuals are to review the entire application or just sections.

4.29 Also, Nova Scotia Environment does not have a process to follow up with reviewers if a response is not received. While comments from some reviewers were provided for each of the applications we examined, not all reviewers responded. The Department did not know if a reviewer did not respond because the request was not received, not enough time was given to review the application, or if the reviewer had no comments to provide.

Recommendation 4.6
Environment should document and implement a process for using government reviewers on environmental assessment applications. The process should include how reviewers are selected, the Department's expectations of reviewers and a follow-up process if responses are not provided by the deadline.

Environment Response: *Agree. The review and update of the EA Checklists will ensure interactions with reviewers are identified, carried out and documented. Timing: June 2017*

Project owners are submitting required information

4.30 The Environmental Assessment Regulations outline the minimum information project owners are to include with their application for an approval and what

the Minister of Environment must consider in making the decision to approve or reject the project. For example, project owners are to provide information on the purpose and need for the project, along with details on the potential effects on groundwater, vegetation, and wildlife in the area. Factors the Minister is to consider in making a decision include the nature and sensitivity of the project area, along with any potential or known environmental impacts on species at risk and their habitats.

4.31 For each of the 22 approved projects selected we examined whether project owners provided the required information and whether the summary of the project included all factors to be considered by the Minister in making a decision. We did not find any significant instances in which the legislative requirements were not met for the applications we examined. In all cases, the information provided by the project owners met the legislative requirements and the Minister was provided with all required information to be used in deciding to approve the project.

4.32 Terms and conditions to manage the risks of the project identified during the application process were attached to each of the approved projects we examined. However, the lack of monitoring of the terms and conditions of approved projects previously discussed weakens the work done by Nova Scotia Environment in deciding to approve a project. The value of the terms and conditions can only be achieved if there is regular monitoring to ensure project owners comply.

4.33 One area in which Nova Scotia Environment can improve its process is the review of an application before it goes to the Minister for a decision. When staff within the Department complete their review, a summary of the project and associated risks is compiled and forwarded to the Minister. However, there is no review of the summary to ensure the details and risks of the project are accurately and completely captured.

Recommendation 4.7
Environment should complete and document a review of information sent to the Minister of Environment for deciding on whether to approve or reject a project.

Environment Response: *Agree. A routing sheet will be instituted to ensure a review of information is in place before it is sent to the Minister. Timing: June 2017*

Appendix I

Audit Objectives and Scope

In winter 2017, we completed a performance audit at Nova Scotia Environment on the Environmental Assessment program. The audit was conducted in accordance with sections 18 and 21 of the Auditor General Act, and auditing standards of the Chartered Professional Accountants of Canada.

The purpose of the audit was to determine whether Nova Scotia Environment is appropriately reviewing environmental assessments to ensure potential impacts to the environment are avoided or reduced, monitoring the risks identified, and taking action when necessary.

The objectives of the audit were to determine whether Nova Scotia Environment:

- conducted environmental assessments that are consistent with relevant legislation, policies and procedures;
- has processes to monitor compliance with terms and conditions of environmental assessment approvals;
- has a process to evaluate the effectiveness of the environmental assessment program in reducing the impact of adverse effects or significant environmental effects.

Generally accepted criteria consistent with the objectives of the audit did not exist. Audit criteria were developed specifically for this engagement. Criteria were accepted as appropriate by senior management of Nova Scotia Environment.

Our audit approach included an examination of documentation of systems and processes; examination of legislation, policies, guidelines, standards, and other documentation; and testing compliance with legislation, policies, guidelines, and standards. We interviewed management and staff at Nova Scotia Environment. Our main audit period included activities between January 2013 to August 2016. However, we examined activities outside of this period when necessary.

We did not comment on the accuracy of the information provided by project owners included in environmental assessment applications, nor did we comment on the technical feedback provided on applications by government reviewers. Our work focused on whether the required steps were followed in issuing environmental assessment approvals and whether the Department ensured project owners met the terms and conditions of the approvals.

APPENDIX H-13

PRINCE EDWARD ISLAND LEGISLATIVE ASSEMBLY

Speaker: Hon. Francis (Buck) Watts

Published by Order of the Legislature

Standing Committee on Agriculture and Fisheries

DATE OF HEARING: 1 FEBRUARY 2019

MEETING STATUS: PUBLIC

LOCATION: LEGISLATIVE CHAMBER, HON. GEORGE COLES BUILDING, CHARLOTTETOWN

SUBJECT: BRIEFING FROM REPRESENTATIVES OF ENVIRONMENT AND CLIMATE CHANGE CANADA RE: PROPOSED WASTE WATER TREATMENT PROJECT AT NORTHERN PULP

COMMITTEE:

Allen Roach, MLA Montague-Kilmuir [Chair] (replaces Hal Perry, MLA Tignish-Palmer Road)
Dr. Peter Bevan-Baker, Leader of the Third Party
Hon. Richard Brown, Minister of Communities Land and Environment (replaces Hon. Paula Biggar, Minister of Transportation, Infrastructure and Energy)
Jamie Fox, MLA Borden-Kinkora
Hon. Sonny Gallant, Minister of Workforce and Advanced Learning
Colin LaVie, MLA Souris-Elmira
Hon. Chris Palmer, Minister of Economic Development and Tourism

COMMITTEE MEMBERS ABSENT:

Alan McIsaac, MLA Vernon River-Stratford

MEMBERS IN ATTENDANCE:

Darlene Compton, MLA Belfast-Murray River

GUESTS:

Environment and Climate Change Canada (Caroline Blais; Geoff Mercer)

STAFF:

Ryan Reddin, Clerk Assistant (Research and Committees)

Edited by Hansard

The Committee met at 10:00 a.m.

Clerk Assistant (Reddin): Good morning everyone.

The Chair of the committee, Mr. Perry, is absent today, so, I'll open the meeting to ask for a nomination for a temporary Chair.

Mr. R. Brown: Allen Roach.

Clerk Assistant: Hearing Mr. Roach; any other nominations?

An Hon. Member: I'll second that motion.

Clerk Assistant: All in favour please signify by saying "aye".

Some Hon. Members: Aye!

Clerk Assistant: Any opposed say "nay".

Motion is carried.

Mr. Roach, please take the chair.

Chair (Roach): Good morning everyone.

First of all I'd like to welcome our guests that are here today; welcome to Prince Edward Island. Welcome to the cold weather, but I guess no matter where you go in Canada today you're going to get the same.

We're here today to talk about the Northern Pulp effluent treatment plan and what's taking place in Nova Scotia. Just before we get started I'd like to – anyone who's going to speak – the first time you speak I would ask you to identify yourself and that way our good folks over in the corner will be able to know who's speaking when they're doing their transcribing over there.

The other thing I've been doing at committee meetings is, when it comes time for questions later on, I'd like to give each minister and MLA the opportunity to ask three questions and then that way everybody in the room gets an equal opportunity to ask questions and at the end of that, if there's more time then we'll just start that process again. That seems to work quite well, so unless there're any objections, I'd like to continue it that way.

Having heard none; thank you.

I would invite whoever would like to speak to go ahead.

Could I also get an adoption of the agenda for today?

An Hon. Member: So moved.

Chair: Thank you.

Okay, Geoff and Caroline, whoever would like to go first?

Geoff Mercer: Thank you Mr. Chair, it's a pleasure to begin.

Good morning everyone, it's a pleasure to be here today in front of the Standing Committee on Agriculture and Fisheries. It's an absolute pleasure to be here in Charlottetown; of course on lovely Prince Edward Island despite the frigid Canadian winter.

Mr. Chair, my name is Geoff Mercer; I have the pleasure to be the Regional Director General for Atlantic and Quebec Regions of Environment and Climate Change Canada. I'm headquartered in Halifax, Nova Scotia and I'd like to introduce my colleague Ms. Caroline Blais. Ms. Blais is the director responsible for forest products and the policy administration of the pollution prevention provisions. You'll hear that term today, the pollution prevention provisions we refer to as subsection 36(3) to 36(6) of the *Fisheries Act*, with, and under, the administration of Environment and Climate Change Canada. I sincerely appreciate Caroline's travel last night from Ottawa. Thanks for being here, Caroline.

In follow up to my department's letter to this committee dated on the 19th of December, we are here today to provide more details on the Environment and Climate Change Canada's responsibilities under section 36(3) of the *Fisheries Act*, as they relate to the regulations for the release of effluents into waterways as was requested in the letter we received.

It's important to understand that Environment and Climate Change Canada is a science-based department. We develop policies, we deliver programs, we make

decisions based on scientific evidence. The departments programming focus is on minimizing threats to Canadians and their environment, including climate change, conserving and restoring Canada's natural environment and providing data and information to Canadians to make informed decisions on weather and weather conditions.

Secondly, please note that we are a regulator. As a regulator, the department is committed to maintaining a regulatory system in Canada that is evidence-based, effective, efficient, transparent and adaptable. We enforce Canada's environmental laws. Those laws include – just to name a few – the *Canadian Environmental Protection Act* which was recent – amended in 1999 last. We refer to it as CEPA (CEPA 99). The *Species at Risk Act*, you'll hear the acronym SARA used for that; the *Migratory Bird Convention Act, 1994*, just to name a few pieces of the legislation that we enforce. But we are here today to talk to you about the pollution prevention provisions, remember section 36(3) to 36(6) of the *Fisheries Act*, which is why we're here.

Ms. Blais will provide the committee with information on the department's rules and responsibilities for the pollution prevention provisions of the *Fisheries Act*, and specifically, the Pulp and Paper Effluent Regulations.

Following our presentation, we look forward to receiving any questions you may have on these regulations.

So, with further ado, Mr. Chair, I'd like to ask my colleague, Ms. Blais to begin with her presentation.

Caroline Blais: Thank you, Geoff.

Good morning everyone; Chair, members of the committee, thank you for the opportunity to appear here today. My name is Caroline Blais; I'm the Director of the Forest Product and *Fisheries Act* Division at Environment and Climate Change Canada. My team and I are responsible for implementing the Pulp and Paper Effluent Regulations.

So, I'd like to start with some information regarding the *Fisheries Act*. The *Fisheries Act* is the oldest piece of environmental legislation in Canada. It was first enacted in 1868. It applies to all Canadian fishing zones, territorial seas and inland waters, so that's our basis.

The Minister of Fisheries and Oceans is responsible for most of the act. The minister of environment is responsible for the pollution prevention provision for all activities, except aquaculture, the control and eradication of aquatic invasive species and aquatic pests. That stays with the Minister of Fisheries and Oceans.

The sharing of the responsibility was confirmed in 2014 through a designation Order in Council that gave the minister of the environment primary responsibilities for the pollution prevention provision and those are the section 36(3) to 36(6).

There are two of these subsections that are key: first the subsection 3, which really prohibits the deposit of any deleterious substance pollution in waters frequented by fish, or in any place under any circumstances where it may enter such water unless authorized by regulations. That's our basis.

Second, the Governor in Council may make a regulation under subsection 36(5) authorizing certain deposit under conditions. In 1992, the Government of Canada promulgated the Pulp and Paper Effluent Regulations also known by its acronym PPER; we love acronyms. The regulations apply to all pulp and paper mills in Canada by setting national effluent quality standards.

The purpose of the regulations is to manage threats to fish, fish habitat and the use of fish by humans, i.e. when we eat the fish, by limiting the deposit of deleterious substances into fish bearing waters. All 90 pulp and paper mills in Canada, across Canada, must comply with these regulations.

The regulations set maximum quantities of amount of biochemical oxygen demand matter and suspended solid that may be deposited by mills and prohibit the deposit of effluent that are acutely lethal to fish. I will explain some of these terms.

Biochemical oxygen demand matter; it represents the amount of matter that consumes oxygen dissolved in water. It is determined using biochemical oxygen demand test, which is the measure of dissolved oxygen in the water consumed by the organisms to break down the organic material present in the effluent. It is used as one of the measures of the degree of pollution in that effluent. The higher the value, the more pollution in the effluent. So it is important to limit BOD matter so that an effluent does not reduce the available oxygen in the receiving environment. If oxygen levels in water are too low, aquatic organism will be negatively impacted.

Total suspended solids are essentially solids that are not dissolved in the water and are also a measure of pollution. This is an important perimeter to control because high levels of suspended solid can harm fish gills, so those are two substances that are regulated under PPER.

Finally, acute lethality to fish is determined when more than 50% of rainbow trout die when they are placed in the effluent at 100% concentration level over a 96-hour period. This test is used to make sure that the effluent as a whole does not kill fish.

The maximum quantity set in the PPER are national standards based on what was achievable by pulp and paper mills using secondary wastewater treatment system at the time the regulations were developed. The regulations sets a number of conditions that pulp mills must meet in order to be authorized to deposit biochemical oxygen demand matter and suspended solids.

The regulatees must; install, maintain, calibrate monitoring equipment, monitor effluent and submit monthly report of the monitoring results and production information, notify an inspector without delay of any results of a test conducted that indicates failure or non-compliance, submit identifying information, prepare and update annually a remedial plan, prepare an emergency response plan, submit information on all outfall structures and deposit effluent only through these outfall structures, comply with the requirements of environmental effects monitoring studies and keep records on sites for inspections.

Environmental effects monitoring done by the mills is the ultimate performance measurement tool for the Pulp and Paper Effluent Regulations. It measures, directly in the receiving environment, the effects of effluent on fish, fish habitat and human use of fisheries resources to assess how well the regulations protect fish, fish habitat and the use of fish by human.

This is achieved by comparing a number of measures taken in the area exposed to the effluent and a similar area not exposed to the effluent. These measures include data on water, sediment, fish, fish tissue, fish habitat. Environmental effects monitoring also includes sub-lethal toxicity of final effluent. So, this test is performed in a laboratory to provide information on the potential effect of effluent on biological component in the receiving environment and it's a longer test.

Under the regulations, mills are required to identify and investigate potential effects on their effluent on fish, fish habitat and the use of fisheries resources. When environmental effect studies show effects as a result of the discharge of the pulp and paper effluent, mills are then required to conduct studies to understand the causes and identify potential solutions to mitigate these effects.

Now I'd like to explain the results that have been achieved by the Pulp and Paper Effluent Regulations since it came into force in 1992. Since then, mills across the country have made significant improvement in their effluent quality; in most cases by implementing secondary biological treatment system. Between 1987 and 1996 – so total discharge of suspended solids and biochemical oxygen demand matter decreased approximately by 60 and 90% – so that's across the country. Compliance rates with the regulations is high and based on the self-reported data, over 97% attest that mills across the country conduct are compliant with the regulations.

Despite this high level of compliance with the existing effluent standard, the environmental effect studies have shown that the effluents from 70% of the pulp and paper mills across the country are having an effect on fish and/or, depending, fish habitat.

So on the national basis, like the most prevalent impact of mill effluents are eutrophication, which is when there is too much nutrient in the body of water and reduced size of reproductive organs in fish. Eutrophication can lead to oxygen depletion and decrease in species diversity. Reduce reproductive organs in fish can lead to reproduction in species, diversities and imbalance in the fish communities.

In taking this information – in September 2017, the department launched a process to modernize the Pulp and Paper Effluent Regulations.

The modernization is focused on four key areas: 1) winding the scope of the regulations to capture new and innovative products being produced by the sector; 2) reviewing the regulatory limits for existing and new deleterious substances 3) improving the administration of the regulations and; 4) streamlining the reporting and administrative requirements.

A key area of the modernization is increasing environmental protection. The department has publicly proposed to reduce maximal allowable biochemical oxygen demand matter and suspended solids and to add new substances to regulate, such as nutrients.

A first round of engagement with interested parties occurred between fall of 2017 and spring 2018. A second round of engagement is planned for winter/spring 2019.

In closing, I would to emphasis that notwithstanding the evolution of the regulations effluent from pulp and paper mills across Canada are regulated and the effluent of any new treatment facility at a mill in Canada would be subject to these regulations.

That concludes my remarks and happy to answer any questions.

Chair: Thank you both very much.

First question is from MLA Compton.

Ms. Compton: Thank you, Chair. I want to thank both of you for coming in today.

I'm not actually on this committee but it's of great impact to my district and had a lot of constituents reach out. We've had a number of people come in, including Northern Pulp and it seems every question we asked it was someone else's department or no, we can't answer that, or no, that's environment, or no, that's fisheries.

I guess my first question would be – looking down the road, I mean 50 years ago they thought Boat Harbour was going to be the answer and we now know that it wasn't. Fifty years down the road what are we going to be saying about the Northumberland Strait and the impact that this is going to have on fishery? I don't know if you can comment.

Thank you for all that information; it was a lot to process and maybe we could have that given to us in written form or online, that would be great. But if you can just answer how we can be assured that 50 years down the road this process – which the only answer we've gotten is it's going to better than it was – is not going to be better than it was – or is going to impact the environment and the fisheries.

Geoff Mercer: I think I'll start general. Thanks very much MLA Compton for the question, first and foremost.

Environment and Climate Change Canada like I said in the beginning is a science-based department and we're a regulator. The development and implementation of the Pulp and Paper Effluent Regulations in 1992, as my colleague Ms. Blais indicated, markedly improved the performance of mills in protecting the environment, particularly, the decrease in toxins or furans in the environment. Toxins and furans are cancer-causing agents that were released up until then.

In today's world in environmental standards, we use the absolute best practices that are available and the leading class science that we can in this country to make sure that the regulations are written in a way and are applied consistently across this county, as Caroline has indicated, from coast to coast to coast in all 90 mills. When those regulations are applied consistently and with world class enforcement officers that we have through our environmental

enforcement officers program, then we have absolute certainty that those regulations are being applied as the laws are written in Canada.

Ms. Compton: I wondered if either of you could answer the question as to, if there was a new mill being built that was proposing the same effluent treatment, would that be approved through the regulations that both your departments have?

Caroline Blais: Thank you for the question.

As a regulator, a regulation does not approve single projects. So if there is a new mill, from the beginning, they will be subject to the effluent standard. We don't prescribe the technology; they just have to meet the effluent standard for biochemical oxygen demands, suspended solid acute lethality of the existing reg. When the new regs are coming into force they will be subject to those levels.

Ms. Compton: You did state that of the mills that are existing, 70% of those mills are having an impact on the fish that the effluent is going into the water. I'm not even sure I'd ask the question, but the concern that we have here is it's going to ruin the fishery in the Northumberland Strait. If right now 70% of the mills which supposedly meet the criteria by both the regulators that are represented here, there's still a problem and how do we move forward from that? If we take 70% of the fishing in our Strait or 70% of the mills, this is included I'm sure – and maybe can you answer: Is Northern Pulp one of the mills and the effluent coming out of there now is affecting the fisheries?

Caroline Blais: So effluent standards – okay, so I'll answer the question (Indistinct) two steps. The first part of the question is that we are aware that despite the high level of compliance with the effluent standard, effluents across Canada are having an impact on fish, which is why in September 2017, the department launched a process to modernize these regulations, so to update the effluents limit. The second part is, if Northern Pulp has an impact and our information looking at their (Indistinct) studies, we found that yes, they have an impact on fish habitat and the company is at the stage where they are looking for the cause of the impact and their last study is posted on their website. That's where they are in the process.

Ms. Compton: Do you want me to keep going?

Chair: No.

MLA Fox.

Mr. Fox: Thanks, Chair. Thank you very much for attending today.

In your submission there, you talk about installing and maintaining and calibrating and monitor equipment. I'm interested in: How often do the inspectors actually check and verify that the equipment they're using to test the water is actually calibrated?

Caroline Blais: Our colleagues in the enforcement branch have a prioritization exercise and on a yearly basis they kind of look at all of their regulations across the department and the regulatee and to set up a schedule to go and inspect a number of facilities, including pulp and paper mills. In terms of the exact frequency, I don't have that information here, but they do have a process to go and inspect and verify those documents.

Mr. Fox: Chair, a follow up to that, is it possible to get a list of how many times inspectors attended Northern Pulp and found them to be non-compliance to the act or the regulations, or the standards that are required?

Caroline Blais: We'll take that information back (Indistinct)

Mr. Fox: Thank you.

If we recognize that the effluent going into the Strait or into a waterway is above the temperature of the water and we know that that rise in temperature affects the oxygen levels in the water which has a negative effect on the species, any species of fish in the water – we also know that climate change is real – why would we allow any substance to go into a waterway that is above the average temperature of the water, which is actually worsening the climate effect change?

Gunn's pulp mill permit lapses so land now for sale

31 August 2017

Andrea Dawkins

One of Tasmania's most controversial issues – a proposal for a $2.5 billion pulp mill at Bell Bay – is finally over. Sources: The Mercury, The Examiner, The Bendigo Advertiser

Permits to build the pulp mill, originally proposed by collapsed timber giant Gunns Limited, lapsed.

A spokesman for Gunns Limited receivers, Korda Mentha, said it would not contest the lapsing of the permits because there was no prospect of a developer being interested.

He said Korda Mentha would instead try to sell the land at Bell Bay and that they had been obliged to wait until the permits lapsed before proceeding with an attempt to sell the land.

"Receivers will now be able to start serious discussions with parties who expressed an interest," he said.

The land, with or without the permits, has been on the market for more than two years.

Gunns Ltd spent about $230 million on research and getting the pulp mill permits in place before collapsing in 2012.

The spokesman said conditions in the international pulp market meant a sale would not occur.

The pulp mill saga ran from 2007 and involved political drama over the approval processes and huge opposition from environmentalists.

Gunns bankers ANZ bank would not finance the mill and Gunns attempted to bring in partners without success.

Daily Timber News Archives

The Greens will table a bill when Parliament resumes next month to repeal the Pulp Mill Assessment Act and bury the project for good.

The previous Labor government, with support from the Liberals, extended the permit conditions under the act to this year

Bass Greens MHA Andrea Dawkins said the party would table legislation in the spring session of Parliament to repeal the entire act.

"The expiration of the pulp mill permits means the Tamar Valley community is one step closer to ending this sorry saga that has plagued them for fifteen years," Ms Dawkins said.

"People within that community were vilified and abused for standing up for their right to live in a place with clean air and water."

A previous move to repeal the Pulp Mill Assessment Act was defeated in 2011.

The state government have said it would not be offering the project any more support.

[redacted]General Manager
Northern Pulp Nova Scotia Corporation
PO Box 549, Station Main
New Glasgow, NS
B2H 5E8

Dear [redacted]

RE: Review of Preliminary Receiving Water Study for Northern Pulp Effluent Treatment Plant Replacement, Pictou Harbour, Nova Scotia

As you are aware, the Northern Pulp Effluent Treatment Plant replacement requires a Class I Environmental Assessment (EA). This letter provides results of a preliminary review done by the department of the above mentioned receiving water study. This study is expected to form part of the registration package that you would provide when Northern Pulp officially registers the project for EA. Please note, this represents only a preliminary examination of the report and does not preclude further assessment and consideration of information that is received as part of the EA.

As this review was undertaken only by Nova Scotia Environment (NSE), you are advised to seek input from Fisheries and Oceans Canada and Environment and Climate Change Canada, as well as other federal and municipal agencies, to ensure their requirements are addressed prior to final design of the treatment facility and selection of the discharge location. The intent of this input is to assist you in finalizing the design and preparing your documents for Environmental Assessment and does not in any way encumber the Minister's decision following the EA process.

Following are key comments on the report:

1.0 Based upon the modelling data provided, the report identifies the following maximum allowable concentrations:

- Maximum daily flow - 85,000 m^3
- BOD_5 – 48 mg/L
- TSS – 48 mg/L
- Colour – 750 TCU*
- AOX – 7.8 mg/L
- Nitrogen – 3.0 mg/L
- Phosphorous – 1.5 mg/L
- pH – 7-8.5

  * Note: color must achieve background concentrations prior to the effluent surfacing at 90 meters.

[redacted] 18(1)(a)

Department reviewers are generally supportive of these numbers. They make sense from a science perspective. As mentioned however, additional information may become available during the EA that will also need to be assessed. We are however comfortable with using these numbers for the design of the project.

2.0 NSE is aware that current data from the facility indicates possible exceedances at point C for many of the parameters. As part of the EA, Northern Pulp must demonstrate that the new treatment facility can achieve the numbers highlighted in 1.0 above. If any of the parameters, including maximum flow, require modifications to the Mill itself to achieve the volumes and concentrations modelled in the study, Northern Pulp must also submit a plan to the Department indicating what changes are required to the Mill to achieve the maximum concentrations. Should additions/modifications be required to the Mill itself, an application for amendment to the current Industrial Approval will be required prior to implementation of any modification.

3.0 With respect to the current Industrial Approval the maximum Chemical Oxygen Demand (COD) concentration discharged from the Kraft Pulp Mill into the effluent treatment facility is:

- COD – 950 mg/L (570 mg/L at point of discharge, assuming a 40% reduction in the SBR)

4.0 NSE Accepts that a flow of 85,000 m^3/day is appropriate for design of the new system. However, Northern Pulp must continue to meet the current maximum daily water intake requirement of 92,310 m^3 outlined within the existing approval that expires January 30, 2020.

Should you have any questions or concerns regarding this information, please do not hesitate to contact me at 902-483-2696 or via email at helen.macphail@novascotia.ca.

APPENDIX H-16

Lack of public consultation ahead of Northern Pulp's submission of Environmental assessment sparks backlash

Brendan Ahern (brendan.ahern@ngnews.ca)
Published: Jan 16 at 2:13 p.m.

An aerial view of the Town of Pictou, with the Northern Pulp mill across the harbour. August 21, 2014. - Christian Laforce

Pictou

Northern Pulp's decision not to hold public consultations before filing its environmental assessment has received blowback from groups representing Northumberland fishermen.

In a statement issued from Friends of the Northumberland Strait, the group decries the company's decision, stating that, "Concerned citizens and fishermen say they are appalled that Northern Pulp

does not plan to hold any open houses or public consultation before filing for environmental assessment."

The statement emphasizes Northern Pulp's past promise to hold further open house events designed to keep the public up to date on the company's plan.

"We were told Northern Pulp were wanting to be transparent during this process," said Friends of the Northumberland Strait president Jill Graham-Scalan in an interview. "They had promised us during that time that as the studies they were conducting on the route and the receiving waters were completed that they would be making those studies available to the public."

An addendum to Northern Pulp's water receiving study was posted after the press release, but Graham-Scalan says that this is not the level of transparency that was promised form the company back in December 2017.

With the company's environmental assessment being submitted at the end of January, Graham-Scalan says that it could be difficult to properly analyze the information and provide feedback.

"Not only do we have to read it, we have to absorb and reply to it," she said. "That 30-day period is the only period of time that the public has to come up to speed on the proposal and respond to the province in a way that is complete."

Northern Pulp has cited 'significant' delays and a need to move forward under an impending deadline as it's reason for filing the assessment without holding the open houses.

"We've experienced a significant number of delays through the fall in attempting to get some of the information compiled," said Northern Pulp director of communications, Kathy Cloutier. "We're at a point now where we want the project to move forward."

Cloutier added that the blockades Pictou Harbour by strait fishermen of the company's survey boat was a major factor in the need to push ahead to make up for the lost time.

When asked if the incomplete survey of the sea-floor will impact the quality of environmental data submitted to the province, Cloutier said that the only gaps will have to do with the pipe's construction.

"There may be some constructability gaps, but the environmental assessment will be a complete document."

"Another major factor to delays is the number of studies and expanded studies that were done," said Cloutier. "When the process began there were seven studies that we were aware that we'd need to submit for an environmental assessment. Since then we've moved from seven to 17, to 20, we're now at 28."

The validity of that data revealed in those studies will then be determined by the provincial assessment.

After Jan 31. Cloutier says that that information will be in the hands of the public and the provincial government.

"I can't speak to a government process, but what I can say is that there will be time for people to submit comment, and that will help the minister."

The statement issued by Friends of the Northumberland Strait remains skeptical that Northern Pulp's assessment will accurately measure the outfall's effect on marine life in the strait.

"Knowing the composition of the treated effluent they plan to release is critical," wrote president of the Northumberland Fishing association Carl Allen. "We've asked for this information for almost a year, and have never received it. If the effluent is as harmless as Northern Pulp tells the public, why haven't they provided the information?"

NOV 3 0 2017

Bruce Chapman, P.Eng., General Manager
Northern Pulp Nova Scotia Corporation
PO Box 594, Station Main
New Glasgow NS B2H 5E8

Dear Mr. Chapman,

Re: Industrial Approval Clarification

In response to your letter of November 3rd, 2017 and subsequent email of November 14th, 2017 to Deputy Martin and Helen MacPhail, the Inspection, Compliance and Enforcement Division would like to provide clarification on some of the issues raised in your correspondence. Final regulatory effluent discharge limits will be established once the environmental assessment process is complete.

Northern Pulp's receiving water study for flow, BOD_5, TSS, Colour, AOX, Nitrogen, Phosphorous and pH will be taken into consideration. Requirements of the current industrial approval for influent COD reductions from benchmark concentrations by 2020 as submitted by Northern Pulp on December 14, 2016 and accepted by NSE on February 27, 2017 will also be considered. The upcoming environmental assessment will also be used to establish those limits. Currently, NSE has indicated support for discharge concentrations as indicated in the October 5th, 2017 correspondence from Helen MacPhail. These effluent concentrations may be subject to change, depending on the outcome of the environmental assessment.

In general, NSE considers operational variations when determining compliance for items such as monitoring parameters through the industrial approval process. Industrial approval application submission requirements include a detailed engineering report. Northern Pulp will also need to submit plans for an effluent treatment plant design which will meet the effluent discharge requirements, taking all the factors listed above into consideration.

With respect to the regulation of COD, as you may recall, during early industrial approval discussions, Northern Pulp indicated it did not wish to have a study style approach to reduction of black liquor spills. Instead, the company requested the approval contain a compliance limit your company could work to achieve. Through discussions with third-party experts, it was recommended the best way to manage black liquor spills is through regulation of COD. NSE recognizes COD is not a widely-regulated parameter in North America for the pulp and paper industry, although there are individual facilities which do have COD limits within their individual operational permits. During discussions between Northern Pulp and NSE following Northern Pulp's appeal of the industrial approval, Northern Pulp agreed that an influent concentration of 1900 mg/L was a reasonable benchmark for COD reductions. Northern Pulp confirmed it could achieve a 50 per cent reduction from this benchmark by January 2020 would be achieved in the December 14, 2016 submission. That is why correspondence from the Environmental Assessment branch regarding effluent discharge limits references the current industrial approval requirements for COD rather than the receiving water study, as not to create a conflict between the two.

.../2

Intended for Public Use

With respect to your comment from your email dated November14th on the renewal of the industrial approval and the ability to start discussions on a future IA, NSE offers the following comment. As you have stated and agree, there are many items in a future IA that will be determined once the EA process is completed. NSE agrees with this comment and recognizes that large industrial applications such as a pulp and paper approval can take several months of review and discussions between the proponent prior to any issuance of an approval. It is not uncommon for this size of an industrial file to take up to 12 to 24 months to complete a review process. Therefore, it would be prudent for both Northern Pulp and Nova Scotia Environment to begin discussions on a future industrial approval sometime soon. As stated above these discussions will be solely focused on the items in the industrial approval that are not impacted by the future environmental assessment process and those items will be dealt with after the environmental assessment. As this industrial approval process will be completed by the Inspection, compliance and enforcement division of Nova Scotia Environment, you can contact me as the lead for this industrial file at your convenience.

Should you have any further questions or concerns, please do not hesitate to contact me at 902-863-7600.

Regards

APPENDIX H-21

NORTHERN PULP
NOVA SCOTIA CORPORATION
A PAPER EXCELLENCE COMPANY

April 9, 2015

The Honourable Randy Delorey
Minister of Environment
Nova Scotia Environment
PO Box 442
Halifax, NS B3J 2P8

Dear Minister Delorey:

Re: Industrial Approval No. 2011-076657-A01
Appeal pursuant to Section 137 of the *Environment Act*

Northern Pulp Nova Scotia Corporation ("Northern Pulp") appeals Industrial Approval No. 2011-076657-A01 (the "Approval") issued by Jay Brenton of the Nova Scotia Department of Environment (the "Department") on March 9, 2015 for the operation of Northern Pulp's mill in Abercrombie Point, Nova Scotia (the "Mill").

Northern Pulp makes this appeal (the "Appeal") to you, the Minister of Environment, pursuant to section 137 of the *Environment Act*, SNS 1994-1995, c 1 (the "Act"). In the sections below, Northern Pulp states its reasons for this Appeal, outlines its specific objections to various provisions in the Approval and sets out its requested relief.

While Northern Pulp considers it necessary to proceed with this Appeal to protect the long term economic viability of the Mill, Northern Pulp remains open to working with the Department and the Province to achieve a long term solution with respect to the Mill.

SUMMARY OF APPEAL

In summary, Northern Pulp requests that certain provisions (identified below) of the Approval be removed or revised on the grounds that these provisions:

(i) are in breach of the Province's contractual obligations to Northern Pulp under various agreements (which agreements the Department refused to consider in issuing the Approval) and impose conditions that in essence seek to achieve indirectly what the Province is not permitted to do directly, namely, require Northern Pulp to cease using its current effluent treatment facility ("Effluent Treatment Facility");

(ii) impose conditions that are impossible to meet and/or are prohibitory rather than regulatory in nature;

(iii) impose conditions that are too vague or uncertain;

Northern Pulp Nova Scotia Corporation, a Paper Excellence Company
P.O. Box 549, Station Main, New Glasgow, NS B2H 5E8
260 Granton Abercrombie Branch Road, Abercrombie, NS B2H 5C6
T: 902.752.8461 | F: 902.752.9149 | info@northernpulp.com
www.northernpulp.com | www.paperexcellence.com

(iv) are unrealistic and otherwise unreasonable; and/or

(v) are inconsistent with the protection granted to Northern Pulp by the *Freedom of Information and Protection of Privacy Act* ("FOIPOP").

Northern Pulp respectfully requests that you exercise your powers under Section 137(4) of the Act to allow Northern Pulp's Appeal and remove or revise the provisions of the Approval as further outlined in this letter. Doing so would ensure that the Approval contains conditions that: (i) do not breach the Province's obligations under the various agreements between the Province and Northern Pulp and do not effectively require Northern Pulp to change the location of its current Effluent Treatment Facility; (ii) are not impossible to achieve and are regulatory rather than prohibitory in nature; (iii) are not vague or uncertain, (iv) are realistic and otherwise reasonable; and (v) are not inconsistent with the protection granted under FOIPOP.

GROUNDS OF APPEAL

I. Department's Refusal to Consider Province's Contractual Obligations - Section 8(2)(c) of the Act

As you are aware, Northern Pulp and the Province are parties to a number of agreements in respect of the operation of the Mill, including:

1) Memorandum of Understanding dated December 1, 1995 ("MOU");

2) Lease dated December 31, 1995 ("Lease");

3) License Agreement dated December 31, 1995;

4) Indemnity Agreement dated December 31, 1995 ("Indemnity Agreement");

5) Water Supply Agreement dated June 30, 1995 ("Water Supply Agreement");

6) Lease Extension Agreement dated October 22, 2002; and

7) Acknowledgement Agreement by the Province dated May 12, 2008 ("Acknowledgement Agreement").

(collectively, the "Agreements").

Northern Pulp wrote to you on December 18, 2014 in order to ensure that the Department reviewed the Approval in light of the Province's contractual obligations to Northern Pulp under the Agreements prior to issuing the final Approval. In addition, Northern Pulp requested a joint meeting with the Department of Environment and Department of Internal Services to discuss how a long term solution can be achieved in compliance with the terms of the Agreements and the Approval.

In a letter dated January 8, 2015, you responded: "While my department is aware of the existence of agreements between the Province and your company, the Province has maintained independence between the regulation of environmental issues and management of the various agreements with the mill." You encouraged Northern Pulp to meet with Internal Services to discuss the Agreements and any implications that may arise from the issuance of the Approval

by your Department, thereby refusing Northern Pulp's request to meet jointly with Northern Pulp and Internal Services.

Your express refusal to consider the Province's various contractual obligations in issuing the Approval and your refusal to meet jointly with Northern Pulp and Internal Services as requested by Northern Pulp is not in compliance with the mandatory requirement of Section 8(2)(c) of the Act which provides:

> 8 (2) The Minister, for the purposes of the administration and enforcement of this Act, and after engaging in such public review as the Minister considers appropriate, shall
>
> [...]
>
> (c) consult with and co-ordinate activities with other departments, Government agencies, municipalities, governments and other persons; [emphasis added]

Any provision in the Approval which is inconsistent with the provisions of the Agreements is necessarily the result of the Department's refusal to consider those Agreements when it issued the Approval. Northern Pulp submits that those provisions of the Approval are unreasonable due to the failure of the Department to comply with the process of consultation and co-ordination required by its own governing statute in issuing the Approval.

In the Acknowledgement Agreement, the Province acknowledged, agreed and confirmed that each of the Agreements and understandings between the Province and the Mill's prior owner Scott Maritimes Limited ("Scott") are in good standing and will continue in full force and effect for the benefit of Northern Pulp.

Northern Pulp's current owners acquired the shares of Northern Pulp and have continued to invest substantial amounts in the Mill on the understanding that the Province could and would comply with its obligations under the Agreements. It is not unreasonable to anticipate and expect that government will comply with the contracts which it has entered into. It is unreasonable for the Department to issue the Approval with a stated disregard for those contractual obligations. Northern Pulp does not waive any of its rights under any of the Agreements.

Northern Pulp submits that, taken together, the objectionable conditions included by the Department in the Approval that are in breach of the Province's obligations under the Agreements are an attempt by the Department to indirectly achieve the Province's stated goal of closing the Effluent Treatment Facility (see, e.g., Agreement in Principle between the Province and Pictou Landing First Nation dated June 16, 2014). These provisions would force Northern Pulp to apply for an approval for and build an alternative effluent treatment system that meets conditions that would be applicable to a substantially new Mill. This is a goal which cannot be achieved directly under the Agreements which the Province has entered into with the Mill's owners or under the Department's own regulatory jurisdiction. Government cannot do indirectly what it cannot do directly and it is unreasonable for the Department to seek to do so by imposing conditions as part of a regulatory approval process aimed at achieving that indirect goal.

These provisions of the Approval, in addition to being in breach of the Province's obligations under the Agreements, impose conditions which are unreasonable for a mill that was built in the 1960s to meet without requiring that a substantially new Mill be built. While Northern Pulp has

invested in upgrades at the Mill, such equipment modifications will not achieve the requirements of the Approval. The Approval therefore essentially prohibits Northern Pulp from operating the current Mill, and requires Northern Pulp to construct a substantially new Mill, in breach of the Agreements. The cumulative cost and uncertainty associated with the approval and construction of a new effluent treatment system jeopardize the long term economic viability of the Mill and is inconsistent with the Agreements.

Government cannot arbitrarily revoke Northern Pulp's contractual rights under the Agreements with the Province by way of an administrative approval process. Any re-negotiation of Northern Pulp's rights or the Province's obligations under the Agreements must necessarily be the result of written amendment to the Agreements. Northern Pulp approached the Department and the Province indicating that it was prepared to cooperatively work with the Province, as stated in Northern Pulp's December 18, 2014 letter to you:

> "We look forward to working with your department and Internal Services. We hereby request a meeting the first week of January with Internal Services and Nova Scotia Environment to discuss how a long term solution can be achieved in compliance with the terms of the above agreements and the Industrial Approval."

Absent any such cooperation between the Province and Northern Pulp, certain provisions of the Approval cannot reasonably stand given their clear breach of Northern Pulp's rights and the Province's obligations under the Agreements. Any provision in the Approval that is inconsistent with the Agreements must be removed or revised so that the Approval is consistent with the Agreements, including:

A. Definition of Effluent Treatment System – Clause 1(t)

The defined term "Effluent Treatment System" in Clause 1(t) of the Approval now includes the "former stabilization lagoon (known as Boat Harbour)". The defined term "Effluent Treatment System" is included as part of the definition of "Facility" and both terms are referred to throughout the Approval. Northern Pulp has never leased and has never been in control of Boat Harbour. The Mill discharges effluent into Boat Harbour at Point C in compliance with its obligations under applicable approvals and regulations, and has received a broad indemnification from the Province for claims and expenses related to Boat Harbour.

Under Section 4.01(g) of the MOU, the Province remained in possession of and responsible for the stabilization basin. The Lease definition of "Reconfigured Facility" or "Facility" makes it clear that the stabilization basin is not included as part of the Facility. Any terms in the Approval which impose responsibility on Northern Pulp for the stabilization basin known as Boat Harbour ("Boat Harbour") by virtue of:

- including the "former stabilization lagoon (known as Boat Harbour)" into the definition of Effluent Treatment System, including Clauses 5(h) and (i), 6 (h) and (i), 7(j) and (n), 12(au) and 16(b); or

- indirectly including the "former stabilization lagoon (known as Boat Harbour)" into the definition of the Facility, including Clauses 2(c), 3(a), 12(ac) and (am), 24(a) and 25(a),

are inconsistent with the terms of the Lease and Indemnity Agreement.

Northern Pulp therefore requests that the reference to the "former stabilization lagoon (known as Boat Harbour)" be removed from Clause 1(t) of the Approval.

B. Responsibility for Restoration of Stabilization Basin - Clause 7(n)

Clause 7(n) of the Approval requiring Northern Pulp to develop a plan for the long term environmental management and/or rehabilitation of Boat Harbour is expressly contrary to the Agreements. Under Sections 4.01(g) and 4.01(c)(ii) of the MOU, that responsibility falls upon the Province. Further, Section 4.01(f) of the MOU provides that Northern Pulp shall have no obligation or responsibility to restore the stabilization basin, which restoration will be undertaken by the Province. Northern Pulp is entitled to indemnification for any such costs under the broad provisions of the Indemnity Agreement.

Northern Pulp therefore requests that Clause 7(n) be removed from the Approval.

C. Spill Containment Plans – Clauses 14(m) and 14(n)

Clauses 14(m) and 14(n) require Northern Pulp to submit plans to the Department with respect to spill containment. However, Northern Pulp under the Lease is entitled to the use of the Effluent Treatment Facility until 2030 and presently uses that facility for spill containment, which use has been wholly adequate to date.

Requiring Northern Pulp to undertake a new spill containment system when Northern Pulp already has an adequate containment system available to it, which it is contractually entitled to use, provides no additional benefit to the environment and is in breach of the Province's obligations under the Agreements. As Northern Pulp's current system is adequate to protect the public and environment, Clauses 14(m) and 14(n) are inappropriate. Requiring Northern Pulp to undertake a new spill containment system would also be in breach of Northern Pulp's contractual rights under the Agreements. Northern Pulp requests that these Clauses be removed entirely.

D. Water Supply Agreement – Clauses 5(d) and 5(e)

Clause 5(d) of the Approval limits daily water consumption to a rate of 63,000 cubic meters per day by January 30, 2020. For comparison purposes, this represents an intensity of 72.2 m3/Adt. Clause 5(e) of the Approval also requires Northern Pulp to achieve certain water reduction milestones in the meantime. Clause 2.01 of the Water Supply Agreement says that the Province is obliged to continue to supply up to 25 million imperial gallons (or 113,652 m3) of fresh water per day to the Mill until 2021.

The intention of the parties in agreeing to the Water Supply Agreement is clearly contravened by the reductions required by Clauses 5(d) and 5(e) of the Approval. Northern Pulp remains willing to work cooperatively with the Department, as part of an overall negotiation with the Province with respect to the Agreements, to achieve water reductions that benefit the environment but are also practical and realistic. In the absence of such discussions, however, Northern Pulp requests that Clauses 5(d) and 5(e) be removed as they are clearly in breach of the Province's obligations under the Water Supply Agreement and are therefore unreasonable.

E. Surface Run-Off Diversion - Clause 6(c)

The AMEC Report[1] at p. 26 estimates that surface run-off accounts for 2.0 m3/ADt of effluent (rain water entering process sewers). See enclosed KSH Memo[2], at p. 6-8, where KSH has provided more extensive calculations that indicate a similar volume. As a very small fraction of the total flow (less than 1.5% of the total effluent flow for the highest month of the year, April), requiring Northern Pulp to divert surface run-off water into the Pictou Harbour is unreasonable.

Northern Pulp's current practice with respect to the surface run-off stream is to treat it with the Mill effluent, which system (as discussed above in Section I.C.) Northern Pulp is entitled to use until 2030. Clause 6(c) is improper as Northern Pulp's current system is adequate in protecting the public and environment and requiring Northern Pulp to undertake a new surface run-off water diversion program would be in breach of Northern Pulp's contractual rights under the Agreements.

Therefore, Northern Pulp requests that Clause 6(c) be removed.

F. Point D Monitoring – Clause 7(o)

Clause 7(o) requires monitoring at Point D for the parameters in Table 6 of Appendix A. As Northern Pulp's obligations cease at Point C under the Agreements, Northern Pulp cannot properly be responsible for monitoring at Point D, a location in the control of the Province. Northern Pulp therefore requests that Clause 7(o) be removed entirely.

G. Limits in Excess of Pulp & Paper Effluent Regulations – Clauses 6(e), 6(f), 8(d) and 8(f)

Section 4.01(k) of the MOU provides that the Province will impose operating limits on Northern Pulp that reflect and do not exceed or apply more stringently than the standards set out in the *Pulp and Paper Effluent Regulations* (Canada) ("PPER").

As the PPER does not contain limits on COD and TRS, the Approval under Clause 6(e), with respect to COD, and Clause 8(d), with respect to TRS, imposes more stringent operating limits on the Mill than are reflected in the PPER.

Further, to the extent that limits on COD have a limiting effect on BOD, the required reductions in COD under Clause 6(e) of the Approval result in more stringent conditions being imposed on the Mill, notwithstanding that Table 6 of the Approval indicates that limits for BOD are at the rate set by the PPER.

BOD_5 (Biochemical Oxygen Demand) is the amount of oxygen required to biologically oxidize the soluble components in an effluent sample incubated for a 5-day period. It is a measure of easily biodegradable organics that can be utilized as food by naturally occurring organisms. BOD_5 is an indirect measure of how the easily biodegradable organics in the effluent will consume dissolved oxygen in the receiving waters as natural microorganisms consume these

---

[1] The Department indicated to Northern Pulp that AMEC was consulted during the development of the Approval. The April, 2010 AMEC Report entitled "Boat Harbour Return to Tidal Re-Evaluation Final Report" ("AMEC Report") is the latest report that was made available to Northern Pulp.

[2] Memo from KSH Solutions Inc. ("KSH") dated March 31, 2015 entitled "Technical Assistance with Appeal of Final Industrial Approval" ("KSH Memo").

organics, thus potentially affecting flora and fauna due to reduced dissolved oxygen concentrations. COD (Chemical Oxygen Demand) is the amount of oxygen required to chemically oxidize the soluble components in an effluent sample. COD is a measure of all organics (lower molecular weight biodegradable and higher molecular weight non-biodegradable) as well as oxidizable inorganics.

COD will always be the greater of the two, as BOD_5 is a percentage of COD. It is generally accepted that COD and BOD share an empirically demonstrated relationship. Fairly regular relationships exist between COD and BOD_5 for any given industrial or municipal wastewater stream. Once the average COD:BOD_5 ratio for a particular wastewater stream is established, a relatively simple and quick 1-hour COD test can be used to predict BOD_5 with relative reliability. This is why COD tests are often done, but rarely reported. Kraft mill lignin and cellulose contain both low and high molecular weight organics. Therefore, any measures undertaken to reduce COD at the Mill will undoubtedly reduce BOD_5 as well, in breach of the MOU. See enclosed Klopping report at p. 3-4.[3]

As a result of the inconsistency of these provisions with the MOU, Northern Pulp submits that Clauses 6(e) and 8(d) are unreasonable and therefore requests that these provisions, as well as the related provisions at Clauses 6(f) and 8(f), be removed.

H. Precluding Use of Boat Harbour Effluent Treatment Facility – Clauses 5(h), 5(i) and 5(j) and Clauses 6(h), 6(i) and 6(j) and Table 6A

Under the Lease, as extended, Northern Pulp has the right to exclusive possession and occupation of the Effluent Treatment Facility until 2030. The provisions of the Approval that effectively preclude Northern Pulp from using the Effluent Treatment Facility for the Mill's operations are inconsistent with the provisions of the Lease, including Clauses 5(b) and Clause 14 of the Lease.

The effect of Clauses 5(h), 5(i) and 5(j) and Clauses 6(h), 6(i) and 6(j) of the Approval is to require Northern Pulp to apply for an amendment to the Approval if Northern Pulp's modeling of water use reduction projects shows that the final wastewater effluent quality will not meet the requirements of Table 6 of the Approval, without modification or addition to the Effluent Treatment System as configured as of the date of the Approval. The application for an amendment must include a plan for alternative effluent management and/or treatment designed to meet the requirements of Table 6A of the Approval.

These provisions make it clear that the Department intends to require Northern Pulp to discharge its effluent at a treatment facility at a location which has yet to be determined if it is unable to comply with the conditions imposed. By specifically not contemplating or providing a means for compliance to be achieved through modifications or additions to the current Effluent Treatment System, the Province is in breach of the Agreements with Northern Pulp that entitle Northern Pulp to use the Effluent Treatment Facility until 2030. The estimated capital cost of constructing a new effluent treatment plant is in excess of $100 million.

Northern Pulp therefore requests that any Clause in the Approval which contemplates that Northern Pulp cease using the Effluent Treatment Facility prior to 2030, including Clauses 5(h), 5(i), 5(j), 6(h), 6(i) and 6(j) and Table 6A, be removed.

---

[3] Report from Paul H. Klopping dated April 8, 2015 ("Klopping Report"). Paul Klopping has been auditing the Mill since 2005.

I. Rehabilitation Plans – Clause 24

Clause 24(a) of the Approval provides that Northern Pulp must submit a detailed closure plan to the Department one year prior to the decommissioning or closure of the Facility or any part thereof. To the extent that the definition of Facility in the Approval incorporates by reference to Effluent Treatment System the "former stabilization lagoon (known as Boat Harbour)", Northern Pulp refers to Sections I.A., I.B. and I.H. above and submits that any requirement under Clause 24 for Northern Pulp to cease using its current Effluent Treatment Facility, or submit any plan or undertake any costs or rehabilitation with respect to Boat Harbour is in breach of the Lease and the Indemnity Agreement. Northern Pulp is entitled to indemnification from the Province in respect of any cessation by Northern Pulp of the Effluent Treatment Facility and any costs for any rehabilitation of Boat Harbour imposed by the Province on Northern Pulp, under the Approval or otherwise.

Northern Pulp requests that Clause 24 be revised to acknowledge that any cessation of Northern Pulp's use of the Effluent Treatment Facility and any rehabilitation of Boat Harbour are the Province's responsibility and the plans and costs thereof will be assumed by the Province.

II. <u>Prohibitory and/or Impossible Provisions</u>

A. Capital Investment Required to Comply with Approval is Prohibitory - Clauses 5(i), 6(c), 6(g), 6(i), 14(m) and 14(n)

In addition to being in breach of the Agreements as discussed throughout Section I above, Northern Pulp's compliance with the Approval will require Northern Pulp to undertake significant capital expenditures estimated to be in excess of $90 million, to divert surface run-off water to the Pictou Harbour, to implement a new spill containment system, and to reduce COD. See enclosed EKONO Memo, p. 2.[4]

The estimated $90 million in capital expenditures referred to above does not include the capital expenditures to construct a new effluent treatment plant in order to comply with Clauses 5(i) and 6(i) of the Approval, estimated to be in excess of $100 million. This requirement is also in breach of Northern Pulp's rights under the Lease, as discussed in Section I. H. above

The cumulative effect of the capital cost associated with Clauses 5(i), 6(c), 6(g), 6(i), 14(m) and 14(n) of the Approval is effectively the prohibition of Northern Pulp's operation by the Department, instead of the Department's regulation of it.

With respect to COD, Clause 6(g) requires Northern Pulp to develop a plan for additional reductions to achieve a maximum effluent COD of 11,890 kg/day at Point C. This equates to a 77% reduction from the Mill's present operation.[5] Such a provision is not regulatory in nature. It is prohibitory. That is, the Approval through Clause 6(g) has the effect of prohibiting Northern Pulp's activities, rather than regulating them. As discussed further in Section II.B. below, the

---

[4] Memo from Heikki Mannisto and Eva Mannisto dated April 6, 2015 entitled "Possibility to meet COD limit of 11,890 kg/day" ("EKONO Memo").

[5] The average annual COD at Point C for the period of January 1, 2010 to December 31, 2014 is 58.8 kg/Adt. At 873 Adt/day, that equates to 51,350 kg/day at the end of the Approval if the Mill is running at current levels. 11,890 kg/day represents an intensity of 13.6 kg/Adt at Point C.

COD reduction may not even be possible and any capital investments in an attempt to achieve this requirement would be prohibitory.

With respect to surface run-off diversion under Clause 6(c), the new segregated system would require a new sewer network, retention ponds, oil and sediment traps, sample collection, alarms and a mechanism to divert this stream back to the main Mill effluent stream if contamination was detected. This new non-contact outfall will require permits from the Department as well as Environment Canada and the Department of Fisheries and Oceans. Northern Pulp has no guarantee that the Mill will receive these required approvals from these departments.

A new spill containment system under Clause 6(g) is also unreasonable in that it imposes significant cost on Northern Pulp without additional environmental or public benefit and is in breach of the Agreements.

The high capital cost of complying with any or all of Clauses 6(c), 6(g), 14(m) and 14(n) are completely disproportionate to the benefit, if any, to the public and the environment of these measures. The surface run-off diversion requirement is disproportionate given the small fraction of the flow that surface run-off represents and the fact that it is presently treated with the Mill effluent. The spill containment requirement is not only disproportionate but unnecessary because Northern Pulp already has an adequate spill containment system available to it. The Department is aware through the AMEC Report that process technologies for reducing COD to the requirement of Clause 6(g), assuming those reductions are achievable, would be prohibitory. The timelines contained in the Approval for achieving these Clauses are too short for such major construction projects to be completed. Therefore, the conditions in the Approval are impossible for Northern Pulp to meet and are prohibitory.

Through the cumulative effect of these Clauses, and the capital cost associated therewith, the Department is prohibiting the Mill from operating. Instead of regulating the existing Mill, the Department is requiring that Northern Pulp build a substantially new Mill. Provisions of regulatory approvals that prohibit rather than regulate operations are unreasonable and ultra vires. Therefore, Northern Pulp requests that Clauses 5(i), 6(c), 6(g), 6(i), 14(m) and 14(n) be removed from the Approval.

B. COD Reduction is Prohibitory and Impossible to Meet – Clause 6(g)

As noted in Section II.A. above, the proposed COD reduction of 77% under Clause 6(g) of the Approval is prohibitory not only because of the capital investments in order to attempt to achieve this requirement but also because the proposed COD reduction is unrealistic and is essentially impossible for Northern Pulp to meet.

The AMEC Report provided an assessment of the status and operation of the existing treatment facility for the Mill as well as preliminary engineering for several effluent treatment alternatives. The assessment was conducted at the time that the regulatory discharge for the Mill was located at Point D. The AMEC Report concluded that the Mill's Aerated Stabilization Basin ("ASB") was operating well. Since the regulatory discharge point was moved to Point C on July 1st, 2010, there have been no incidences of daily or monthly BOD_5 or TSS being over the limits in the PPER. In fact, all tests have shown that the Mill is well below the regulated limits.

Even though the AMEC Report was based on outdated information and therefore could not recognize the current operational attainments of the Mill, the AMEC Report itself demonstrates that it is simply not possible for the Mill to achieve this COD reduction. As such, the

requirement that the Mill achieve the reduction required by Clause 6(g) amounts to a prohibition of the Mill's operations, rather than the regulation of it, and therefore is unreasonable.

Appendix 2 of the AMEC Report contains the preliminary engineering for the effluent treatment alternatives with mass balances (annual averages and not daily limits). The most stringent case in the AMEC Report, Case 3, completely abandons the Mill's effluent treatment facility and replaces it with a new Activated Sludge Treatment ("AST") system and includes "Significant Improvements & Water Use Reduction", as outlined in section 4.2.3 of the AMEC Report. Drawing #158229-100-6-923 is the mass balance for the New Treatment Plant – Case 3. This Case assumes a 50% reduction in liquor losses will be achieved (20,400 kg/day to 11,400 kg/day). It also assumes marginal increase in production with a design capacity of 908 Adt/day. Incineration of Waste Activated Sludge would occur in the Recovery Boiler, which at present is not permitted in Northern Pulp's Approval. The predicted effluent flow is 65,151 m3/d as an annual average; the new daily limit of 67,500 m3/d required in the Approval is even more stringent than the AMEC mass balance and does not consider seasonal variations.

The predicted COD for Case 3 is 70,900 kg/day. The typical COD removal for a new AST system would be in the neighbourhood of 50 – 60%. Even at the higher end of that removal efficiency (60%), the final COD discharge would be 28,360 kg/day (70,900 kg/day x 0.4). In summary, Case 3 demonstrates that even with significant in-Mill improvements and a brand new AST treatment system, the Mill would still exceed, by more than double, the COD daily limit of 11,890 kg/day at Point C as set out in the Approval at Clause 6(g). AMEC recognizes that other process technologies that were not included in Case 3 would be economically prohibitive to the Mill. The Klopping Report, EKONO Memo and McCubbin Report[6] all agree that the requirement contained in Clause 6(g) is unrealistic and that the associated costs would be significant.

Therefore, the requirement contained in Clause 6(g) of the Approval, as a daily limit representing a 77% reduction from the Mill's current annual average for the Mill's current operations, is impossible for Northern Pulp to meet. The Department included the requirement of Clause 6(g) in the Approval knowing that the AMEC Report says that the Mill cannot achieve that requirement even if the Mill adopted the strictures of Case 3 including installing a completely new treatment system. The requirement of Clause 6(g) is completely untenable, even according to the Report on which the Approval is based. The Department therefore must be considered to have included this provision in order to prohibit the Mill's operations.

The Approval contains conditions that treat the Mill as if it is a new mill and as such the Department has imposed regulatory standards on the Mill that are prohibitory to the existing Mill operating. Provisions of regulatory approvals that prohibit instead of regulate and that are impossible to meet are unreasonable and ultra vires. Therefore, Northern Pulp requests that Clause 6(g) be removed from the Approval.

C. Modeling Deadlines are Impossible to Meet - Clauses 5(h) and 6(h)

Clauses 5(h) and 6(h) of the Approval require Northern Pulp to submit to the Department modeling for all reduction stages along with a list of planned projects required under Clauses 5(e) and 6(e) no later than October 30, 2015.

Northern Pulp's consultants have indicated that it is impossible to complete in-Mill engineering studies and then adequately complete effluent quality modeling to predict Mill wastewater

[6] Report from Neil McCubbin dated April 6, 2015 ("McCubbin Report").

changes for submission to the Department by October 30, 2015. It is not reasonable to require such a deadline considering the impossibility of meeting that deadline as well as the fact that the modeling is for reductions that are not required until 2017.

In Northern Pulp's submission, October 30, 2016 is more reasonably attainable and appropriate. Therefore, Northern Pulp requests that Clauses 5(h) and 6(h) each be revised to change the deadline for this study from October 30, 2015 to October 30, 2016.

D. Regulatory Compliance without Modification or Addition - Clauses 5(i), 6(i) and 6(j)

Northern Pulp is also precluded through Clauses 5(i) and 6(i) from achieving the requirements of the Approval through modification or addition to the effluent treatment system as configured as of the date of the Approval, and through Clause 6(j) from reduction and prevention of liquor losses entering the effluent system. In addition to being contrary to the Agreements as discussed in Section I.H. above, requirements that a proponent achieve regulatory compliance without making improvements to the existing system are prohibitory on their face, and do not serve the public or benefit the receiving environment. Northern Pulp again requests that Clauses 5(i), 6(i) and 6(j) be removed.

III. Vague and Uncertain Provisions

A. New Treatment Facility - Clauses 5(h), 5(i) and 5(j) and Clauses 6(h), 6(i) and 6(j) and Table 6A

In addition to the objection noted in Section I.H. above, the majority of parameters and discharge limits in Table 6A in the event that Northern Pulp is required to discharge its effluent at a treatment facility at a different location have yet to be determined. Those limits are specifically contemplated as being determined based on an unknown location of a new treatment facility and on results of a receiving water study yet to be completed. That receiving water study must meet the satisfaction of the Department, yet the Approval does not indicate any criteria upon which such water study will be considered satisfactory. Northern Pulp considers the requirement to apply for and obtain approval of an as-yet-unidentified discharge location to be unreasonable.

At present, there is an absence of standards and guidelines in Clauses 5(h), 5(i), and 5(j) and Clauses 6(h), 6(i) and 6(j) and Table 6A. These provisions are too vague and uncertain to be considered reasonable. The conditions contain no limitation on the Department's discretion and as a result Northern Pulp has no fair notice of the conditions it must meet. Therefore, Northern Pulp requests that these provisions be removed.

B. COD Reductions - Clause 6(e)

The provisions in Clause 6(e) requiring reductions in COD do not specify or provide a means for calculating the base point for measuring such reductions. These provisions are therefore too vague to be reasonable and therefore must be removed.

IV. Unrealistic and Otherwise Unreasonable Provisions

It is clear that many provisions of the Approval are based on the AMEC Report. However, as noted in Section II.B. above, the AMEC Report is outdated and does not represent the Mill's

current operations and its operational achievements since the date of the AMEC Report. As such, certain provisions imposed by the Department in reliance of this Report are unreasonable.

The AMEC Report ranks Northern Pulp in the 95th – 100 percentile on water usage in Canada. In 2007, the year that Northern Pulp was benchmarked in this 2010 study, the Mill's regulated effluent discharge point was Point D exiting the Boat Harbour basin. In July 2010, the regulated effluent discharge point was moved back to Point C exiting the ASB. Point D is not representative of the Mill effluent flow when compared to other mills because it is downstream of the treatment plant. Effluent flow at Point D is historically 25% higher than at Point C due to surface run-off from the large Boat Harbour basin. Surface run-off was not taken into account in the AMEC Report, and therefore comparisons are not valid. Comparison of Point C data at the end of the treatment process is appropriate for benchmarking purposes. Table I shows the decrease in effluent flow from 2010 forward:

Table I: Effluent Flow Intensity (m3/Adt) – Annual Averages

Regulated Outfall Location	2007	2008	2009	2010	2011	2012	2013	2014
Point D	112	133	129					
Point C				94	89	87	86	88

As the Approval is clearly based on a lack of appreciation for the Mill's current operations, including an outdated report from AMEC which contains conclusions that are no longer correct, the Department has no basis for many provisions contained in the Approval. It is unreasonable for the Department to impose regulatory standards based on a report that relies on almost 10-year-old data and disregards the achievements of the Mill since that time.

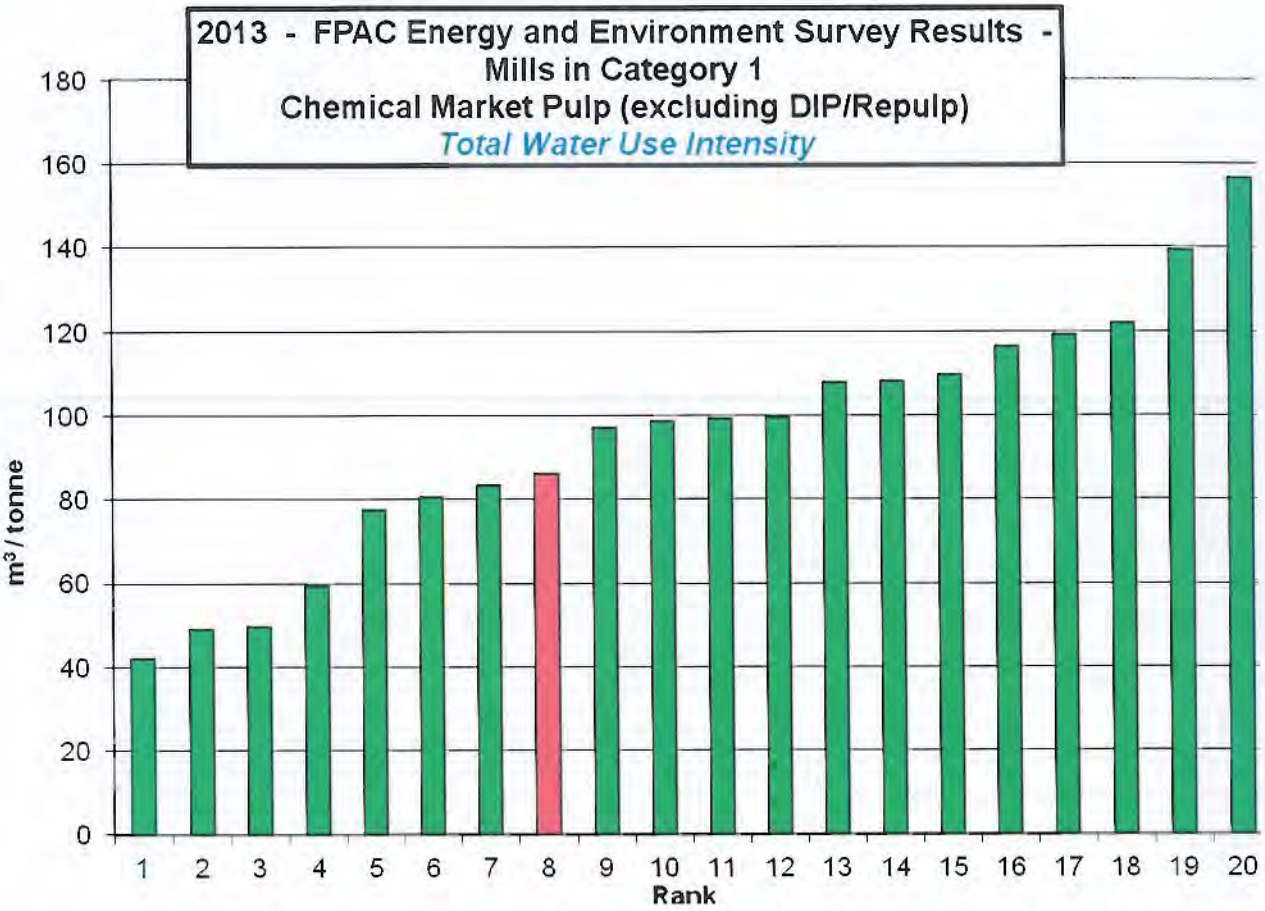
Other provisions in the Approval are unreasonable as they provide little or no additional environmental benefit but impose very significant costs on Northern Pulp and therefore are improper. As well, statements made by the Department in issuing the Approval make it clear that some provisions of the Approval are based on a misunderstanding of or lack of appreciation for the Mill's operations, which make those provisions unrealistic. Some provisions in the Approval are unreasonable as they fail to recognize industry norms or factors outside of Northern Pulp's control. Others are simply inaccurate. Those provisions must therefore be removed or revised as set out in the Sections below.

A. Water Reduction Requirement – Clauses 5(d) and 5(e)

As stated by all effluent experts (Ken Frei and Guy Martin of KSH, Paul Klopping, Neil McCubbin, and Heikki Mannisto and Eva Mannisto of EKONO), the daily limits for water intake and effluent contained in the Approval are highly unusual. Few jurisdictions place flow limits in general on intake and effluent; exceptions are generally where the mill makes up a large percentage of the waters (usually rivers) that it is drawing its water supply from or is discharging effluent into. Mills that ultimately discharge into marine environments do not typically have these restrictions: see KSH Memo, p. 4. The AMEC Report at p. 30 refers to the 2007 EKONO study which also recognizes that such limits will only be placed on mills in certain circumstances, which Northern Pulp notes are not applicable to the Mill.

The requirements related to water reductions in the Approval appear to be based on a mischaracterization of the Mill's water usage. A Departmental document accompanying the

release of the January 30, 2015 version of the Approval stated that "The Mill is a large consumer of water, especially compared to other mills." In fact, Northern Pulp's water usage is average by comparison to other Canadian mills. Enclosed is a copy of the Forest Products Association of Canada survey entitled "FPAC 2013 Energy and Environment Benchmarking Report – Pulp and Paper Sector" dated March 10th, 2015 ("FPAC Report"). The following graph is an excerpt from the FPAC Report. With 20 out of a possible 30 mills reporting, Northern Pulp ranks the 8th best in the survey for water use intensity:



Reductions of water flow of the magnitude contained in the Approval could have negative effects on the biological treatment process and ultimately the receiving water, increasing odour for residents who live in the vicinity of the effluent treatment centre.

As noted in Section I.D above, Clauses 5(d) and 5(e) should be removed from the Approval for being in breach of the Water Supply Agreement. Clauses 5(d) and 5(e) are also unreasonable as they ignore industry norms and are based on a mischaracterization of the Mill's water usage, as a result of the Department's reliance on an outdated report. Therefore, Northern Pulp repeats its requests that these Clauses be removed.

B. TRS Reduction Requirement – Clauses 8(d), 8(e) and 8(f)

The new requirement under Clause 8(d) for water-phase TRS measurements in the effluent are best described by the KSH Memo at p. 14-16. In summary, Clause 8(d) is modeled after

Ontario's new 2014 Air Pollution – Local Air Quality Regulation (which imposes certain air standards, including TRS) and the Ontario Technical Standards to Manage Air Pollution. To Northern Pulp's knowledge, Ontario is the only other province that is introducing this standard. Mills may comply with the Regulation by electing to register under the optional Technical Standard which has phased-in limits for TRS in water entering the wastewater treatment system. The Ontario Ministry of the Environment researched the relationship between TRS effluent loading and TRS in ambient air originally reported by the US EPA. Because the understanding of the relationships of TRS effluent loading and TRS in ambient air are still in their infancy and the influence of other parameters (including pH, temperature and the various types of odorous compounds present) are not well known, the Ontario government introduced this as an optional standard that mills could choose to apply for. Mills that choose to apply will, over time, provide data that will lead to improved understanding of the relationships between effluent concentrations and air quality. The optional nature of the standard gives Ontario the ability to modify the standard as is deemed necessary as information and data become available. By imposing Clause 8(d) in the Approval, the Department has applied the optional Ontario standards as a hard and fast requirement that must be abided by without regard for the outcome of the Ontario mill experiences. If the limits are deemed to be unrealistic, Ontario has allowed room for possible changes; the Department has not.

It is of particular note that Northern Pulp is regulated to fixed TRS limits, including 3-fold reductions in coming years, when the Mill does not have any baseline data. The limits in Clause 8(d) have been set by the Department before any data has been gathered and before it is known if there is even an environmental reason to impose such limits. Ontario has recognized that there is not enough known yet about the relationship between TRS effluent loading and TRS in ambient air to justify the regulation. What is an optional consideration in Ontario because the precise relationship between TRS effluent loading and TRS in ambient air has not yet been demonstrated, the Department has made a mandatory requirement of the Approval. It is unreasonable for the Department to impose a limit before knowing if there is a relationship necessitating that limit.

Northern Pulp has contacted a mill in Ontario and all of the major laboratories in Canada. It appears that no Canadian laboratories (after conferring with their satellite offices) are capable of performing the test required by Clause 8(d), NCASI Method RSC – 02.02. At this point, the closest capable lab that Northern Pulp has found is located in Simi Valley, California. This demonstrates that the Department is imposing a requirement on the Mill is entirely inconsistent with other Canadian jurisdictions.

As noted in Section I.G above, Clauses 8(d) and 8(f) should be removed from the Approval as they are in breach of the MOU. Clauses 8(d) and 8(f) should also be removed as there is no known scientific basis for the limit, which regulators elsewhere have recognized. Northern Pulp does not object to performing testing of TRS in accordance with Table 6 for the benefit of residents, as such monitoring is contemplated in Clause 8(e). However, the imposition of the regulatory requirement to achieve the TRS limits imposed in Clauses 8(e) to 8(f) is unreasonable.

Northern Pulp requests that Clauses 8(d) and 8(f) be removed entirely and that Clause 8(e) be revised to impose only a requirement that Northern Pulp test TRS in accordance with Table 6.

C. Effluent Flow Reduction Requirements – Clauses 5 and 6(a)

The reductions in Clauses 5 and 6 of the Approval are inconsistent. As water use and effluent flow are directly related in terms of the Mill's mass balance, the water use restrictions outlined in Clause 5 of the Approval effectively restrict the effluent limit contained in Clause 6(a) of the Approval to less than 67,500 m3/day or 77.3 m3/Adt. The effect of the water use restrictions in Clause 5 is to impose a greater effluent flow reduction requirement than the Department requires in Clause 6(a).

The AMEC Report (p. 25-26) indicates that consumptive water use (water taken but not returned as effluent) with the power boiler scrubber in operation is estimated at approximately 2 m3/ADt. In essence, from a mass balance perspective, Clause 5(d) is more stringent and practically translates to an effluent limit of 70.1 m3/Adt (72.2 – 2) or 61,200 m3/day. This represents a further reduction of 6,300 m3/day or an additional 9%. The McCubbin Report indicates that the net water consumption of 2 m3/Adt is very conservative and could be as high as 5 m3/Adt, which could lead to even further reduction requirements. KSH indicates that 8% of incoming water supply to the mill would be lost to evaporation. All three consultants (AMEC, Neil McCubbin and KSH) support this reduction of an additional 9-10%.

In addition to the arguments set out in Section IV.A above, the water use restrictions in Clause 5 are unreasonable because they impose conditions that are more onerous than the effluent control limits in Clause 6(a) of the Approval. Therefore, Northern Pulp requests that the water use restrictions in Clause 5 be removed.

D. COD Limits – Clauses 6(d) to 6(j)

The COD limits in Clauses 6(d) to 6(j) of the Approval are based on the outdated AMEC Report and are unreasonable.

Table II below summarizes the Mill COD data at several locations in the treatment plant.

Table II: Effluent COD Intensity (kg/Adt)

Location	2007	2008	2009	2010	2011	2012	2013	2014
Point A	154.6	124.7	103.5	123.4	99.6	92.2	82.5	87.8
Point C	**71.7**	**82.3**	**76.7**	**70.1**	**63.1**	**56.0**	**53.6**	**51.4**
Point D	74.0	78.6	71.3	65.1	62.8	56.0	55.2	50.8

The improvements in COD intensity beginning in 2011 reflected in Table II are in part the result of the Green Transformation Projects carried out by the Mill that year. Continuous improvement initiatives at the Mill have continued to provide COD reduction through to 2014.

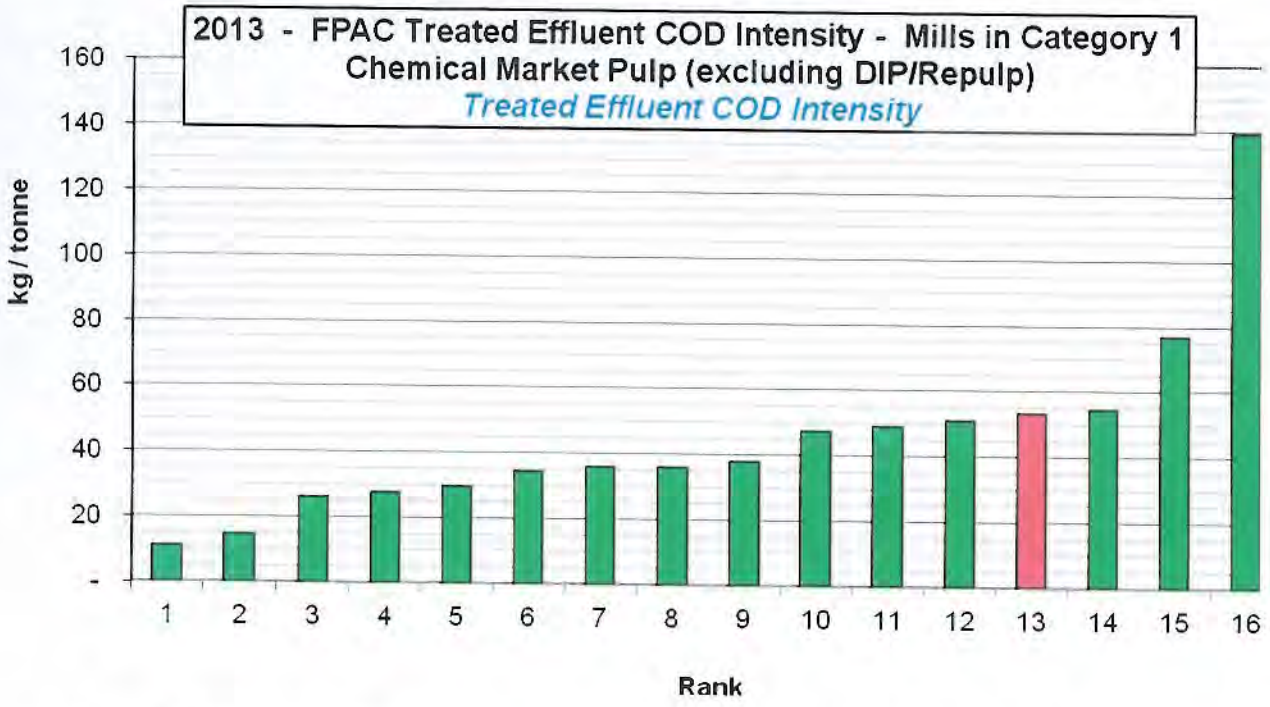
Since the AMEC Report was written, many of the proposed projects for effluent quality improvements identified in the Report have been completed, including: improvements to brown stock washing including two new washer drums and closing of the screen room with true counter-current washing, recycle of PM rejects, Stage 1 DNCG system, sludge removal plan, PB scrubber and a new emergency spill tank. A COD reduction of 30% has been achieved from the 2007 benchmark conducted in the AMEC Report.

Although not clearly stated, Northern Pulp has assumed that the COD reductions in Clause 6(e) of the Approval are based on the five year annual average COD at Point A that was reported pursuant to Clause 6(d).

Northern Pulp's average COD intensity at Point A for 2010 through 2014, as requested in Clause 6(d), is 97.1 kg/Adt. At 873 Adt/day[7], the daily discharge would be 84,800 kg/day. The 50% reduction in COD required by Clause 6(e) would mean a daily discharge of 42,400 kg/day at Point A.

There is very little published data for COD in North America, and virtually nothing from the United States. Data that is published, and all third party data presented in this Appeal, refer to "after treatment" and would be comparable to Point C in the above Table II, not point A (the inlet to treatment).

The Department has recently made statements in media interviews that Northern Pulp has four times greater COD than mills of similar size. This is clearly wrong. The following graph is an excerpt from the FPAC Report. With 16 out of a possible 30 mills in Canada reporting, this graph shows that Northern Pulp clearly does not have four times greater COD than mills of similar size, nor does it have the highest COD discharge.



The AMEC Report indicates (on p. 29) that benchmarking of effluent was done using the widely accepted EKONO study of September, 2007, which is based on 2005 data. The enclosed EKONO Memo compares COD and BOD data from Northern Pulp to the results found in the EKONO database. The EKONO benchmarking and analysis of the new COD limits concludes

[7] 310,000 Adt/year at 355 days is 873 Adt/day at the end of the Approval, assuming that the Mill is able to increase production to this limit by that time.

that the two lowest COD discharge mills are hardwood mills with oxygen delignification, modified cooking, condensate stripping, etc. and the lowest COD discharge in a Canadian bleached softwood kraft pulp mill in the database is 28-30 kg/Adt. The EKONO Memo also concludes that more than 40% of the North American bleached market kraft pulp in 2013 was produced by mills with BOD discharges higher than those at Northern Pulp's Mill. This proves once again that the Department is not working with current data and does not understand the influences of mill process equipment and wood species on COD.

It is clear that the Department was relying on outdated studies and analysis in setting the COD limits in Clause 6. This is based on outdated data and is unreasonable. Therefore, Northern Pulp requests that Clauses 6(d) to 6(j) be removed.

E. Production Limit – Clause 4(a)

Clause 4(a) of the Approval limits the maximum production rate of the Mill to 310,000 Adt/yr. Not only does this Clause prohibit the Mill's future expansion, it also offers no additional environmental benefit. The production capacity of the Mill is and should properly be limited by the existing equipment of the Mill and the other requirements of the Approval. So long as Northern Pulp is in compliance with the other requirements of the Approval, whatever the Mill's production limit happens to be when it complies with those requirements has no environmental relevance.

There is no additional environmental basis or additional public benefit for including in the Approval a provision that arbitrarily limits the production of the Mill. Northern Pulp therefore requests that Clause 4(a) be removed entirely.

F. Phenanthrene Testing – Clause 12(ag)

Clause 12(ag) requires semi-annual testing of Phenanthrene at Surface Water station SW12-3. The trend analysis requested is not warranted because the measurement was at or near the detection limit. See enclosed Dillon Consulting Memo[8]. The requirement of Clause 12(ag) therefore has no justification. It only adds cost to Northern Pulp with no corresponding additional benefit to the environment. The requirement in Clause 12(ag) is therefore unreasonable and Northern Pulp requests that it be removed.

G. Daily Limits for Water and Effluent Usage – Clauses 5(d), 5(e), 6(a) and 6(b)

The reference to water and effluent usage in the Approval in terms of daily limits is contrary to the way that effluent data is compared and benchmarked in the industry. See the AMEC Report and the enclosed EKONO Memo, FPAC Report, KSH Memo, McCubbin Report, and Klopping Report. As stated in the KSH Memo at p. 5, "Effluent flow restrictions are usually stated on an average basis, usually monthly or annually since there is no measurable risk to the environmental [sic] by one day of effluent flow above a certain amount."

The imposition of daily limits for water usage that do not consider seasonality are of particular concern to the Mill. Based on data from the last three years, the Mill's water intake has peaked at 87,000-91,000 m3/day (23-24 million gallons/day), even though the Mill's annual average water usage is 75,000 m3/day (20 million gallons/day). These peak days do not occur during the highest surface run-off months. Rather, they historically occur during the hottest days

[8] Letter from Dillon Consulting Limited dated February 11, 2015 ("Dillon Consulting Memo").

during the summer when the incoming Middle River water is at its warmest and cooling systems are most heavily loaded. Cooling towers will be an essential component of water reduction that will recycle "once-through" cooling water for re-use. Cooling towers are driven by temperature differential (water to ambient air) and relative humidity and are a very effective means of cooling. However, heat transfer during hot, humid spells can be challenging. The cooling towers offer significant water reduction on an annual basis, but daily reductions will be highly influenced by weather. It is therefore clear that the Mill will not be able to operate and comply with the daily water usage requirements of the Approval on certain days of the year. Therefore, daily limits on water usage are unreasonable as they effectively preclude the Mill from operating on a consistent basis.

There is no environmental reason to impose a daily limit in Northern Pulp's circumstances. Northern Pulp therefore requests that all water and effluent usage restrictions in the Approval, including Clauses 5(d), 5(e), 6(a) and 6(b), be revised to be based on yearly averages, not daily limits.

H. $PM_{2.5}$ Contributors – Clauses 9(a) to 9(e)

Clauses 9(a) to 9(e) of the Approval transform the voluntary objectives of the Canadian Ambient Air Quality Standards ("CAAQS") into mandatory compliance requirements without any consideration given to other local sources of $PM_{2.5}$, especially other local heavy industry, wood-burning stoves and other non-commercial sources, or the not insignificant contribution of interprovincial and international transport of $PM_{2.5}$ from other sources.

It is unreasonable to require the Mill's mandatory compliance with the limits in the CAAQS without taking into account other industrial facilities, residential sources and transportation that are also contributors to $PM_{2.5}$ in the area. See KSH Memo, p. 16-18. As the Mill's compliance with Clauses 9(a) to 9(e) is outside of the Mill's own control, such mandatory compliance requirements are unreasonable.

Northern Pulp is confident that the Mill will meet these limits as a contributor; however, imposing mandatory compliance on the Mill without taking into account other contributors is unreasonable. Northern Pulp therefore requests that Clauses 9(a) to 9(e) be revised to acknowledge that Northern Pulp is only required to demonstrate that its relative contribution to the local air quality meets the limits of the CAAQS.

I. Particulate Limit – Clause 9(h)

Clause 9(h) imposes a regulatory limit on the Recovery Boiler for particulate of 77 mg/Rm^3 @ 11% O_2. We understand, based on discussions with the Department, that this limit is based on the performance expected by the manufacturer of the new electrostatic precipitator ("ESP"). This limit does not properly take into consideration the variables that can affect actual boiler performance on a day-to-day basis, particularly in the case of a new ESP attached to an existing boiler. Contrary to North American regulatory convention, the approach taken by the Department in setting the particulate limit for the Recovery Boiler treats the installation of the new ESP as if it were a significant modification to an existing boiler and, as such, treats it as a new boiler and sets emission limits that are in line with such units: KSH Memo, p. 21-22. This is inconsistent with the approach taken in most North American jurisdictions. For example, under the U.S. Air Quality Regulations, the addition and/or replacement of pollution control equipment, such as a new ESP, is not, in itself, considered to be a modification to an existing boiler, and would not result in treating such existing boiler as if it were a new boiler for the purposes of

setting a particulate limit. As the particulate limit imposed by Clause 9(h) fails to recognize that the ESP is being connected to Northern Pulp's existing boiler system and the variables that can affect the performance of that boiler system on a day-to-day basis, Clause 9(h) is unreasonable.

The limit imposed on Quebec's existing recovery boilers of 153.5 mg/Rm^3 @ 11% O_2 represents a more reasonable and appropriate limit, as it represents state-of-the-art performance for a boiler and direct contact evaporator system of the same vintage as Northern Pulp's boiler. See KSH Memo at p. 18-22. Northern Pulp therefore requests that Clause 9(h) be revised accordingly.

J. Middle River Study – Clause 5(f)

Clause 5(f) makes Northern Pulp responsible for conducting a maximum sustainable yield study of the Middle River watershed. In the 47 years of the Mill's operation, neither the Department nor any other stakeholder has ever raised a concern about water usage impacts on the Middle River watershed. The Michelin, Granton facility also draws its fresh water supply from the Middle River and discharges its effluent back into Middle River upstream of the Mill's water supply. As well, the river is dammed to prevent salt water intrusion and the spillway dam is controlled by the Province. See KSH Memo at p. 2. No low-level warnings have ever been communicated to the Mill.

In addition, the December 15, 2015 deadline does not allow for a full year study to cover all seasons which would be normal for this type of assessment, implying that existing data must be used. The responsibility of Northern Pulp to conduct this maximum yield study of the watershed (which is usually directed towards new applicants for a water removal permit) is unreasonable, especially considering the Mill does not have access to or control of pertinent data that would be required to properly complete this study.

Northern Pulp therefore requests that Clause 5(f) be removed.

K. Waste Dangerous Goods – Clause 4(i)

Northern Pulp requests that Clause 4(i) be revised to replace the words "all wastes generated" with "all waste dangerous goods generated" in order to clarify this Clause and ensure its consistency with the preceding Clause 4(h), which deals only with waste dangerous goods.

L. TRS Reporting – Clause 7(m)(i)

The monthly reporting requirement for TRS in Clause 7(m)(i) is internally inconsistent with the reporting requirement for TRS in Table 6 of Appendix A. Clause 7(m)(i) should therefore be amended to include an exception for TRS reporting of every three months.

M. Cardlock Facility Wells – Clauses 12(a) and 12(g)

The Approval at Clause 12(a) requires Northern Pulp to maintain the Cardlock Facility Wells. The Cardlock Facility Wells are owned and operated by Parkland Fuels. Northern Pulp has permission from Parkland Fuels to sample the Wells, but the maintenance of the Wells is not under the control of Northern Pulp. Further, Clause 12(g) requires Northern Pulp to maintain records, including borehole logs, construction details and maintenance records, in respect of the Cardlock Facility Wells. This information is the property of Parkland Fuels and Parkland Fuels has no obligation to provide it to Northern Pulp.

Clauses 12(a) and 12(g) are unreasonable to the extent that these Clauses impose an obligation on Northern Pulp to maintain Wells which are not under Northern Pulp's ownership or control and require Northern Pulp to maintain with respect to those Wells records of information to which Northern Pulp is not entitled. Northern Pulp therefore requests that Clauses 12(a) and 12(g) be revised accordingly.

N. Surface Water Stations – Clause 12(ad)

Several of the Surface Water stations listed do not exist, while other new stations are not listed in Clause 12(ad). See enclosed Dillon Consulting Memo. Northern Pulp requests that this Clause be revised accordingly.

O. Stantec Report – Clause 12(au)

Clause 12(au) is inaccurate as it refers to the Stantec "Hydrogeological and Hydrological Evaluation of the Boat Harbour Treatment Facility Report" as being dated April 30, 2012. Rather, the Report is dated September 28, 2011. Northern Pulp requests that this Clause be revised accordingly.

V. Inconsistency with FOIPOP – Clause 22

The requirements in Clause 22 of the Approval that Northern Pulp provide information to the Pictou Landing First Nation ("PLFN"), including a copy of all reporting information and reports that are required to be submitted under the Approval, is inconsistent with the protection granted to Northern Pulp under FOIPOP. The public accessibility to information under the control of the Department under section 10 of the *Environment Act* is subject to the important restrictions of FOIPOP: section 10(2) of the Act.

Specifically, section 21 of FOIPOP provides that a head of a public body (such as the Minister and Administrator of the Department of Environment) must refuse to disclose information:

> (a) That would reveal
>
> (i) trade secrets of a third party, or
> (ii) commercial, financial, labour relations, scientific or technical information of a third party;
>
> (b) That is supplied, implicitly or explicitly, in confidence; and
>
> (c) The disclosure of which could reasonably be expected to
>
> (i) harm significantly the competitive position or interfere significantly with the negotiating position of the third party,
> [...]
> (iii) result in undue financial loss or gain to any person or organization, or

Much of the information required to be provided by Northern Pulp to the Department constitutes commercial, financial and technical information. That information is supplied to the Department in confidence. The disclosure of this information could reasonably be expected to harm both

Northern Pulp's competitive position as well as its negotiating position with respect to an action that has been brought by PLFN against Northern Pulp. The competitive position of Northern Pulp would be harmed because its competitors in a global market and others having interests adverse to Northern Pulp would become fully aware of the Northern Pulp's commercially sensitive information.

Requiring Northern Pulp to comply with Clause 22 of the Approval is contrary to Section 10 of the *Environment Act* and Section 21 of FOIPOP. The Department through the Approval is circumventing the due process provided for under FOIPOP and the procedural fairness afforded to Northern Pulp with respect to the release of Northern Pulp's confidential and commercially sensitive information to third parties. The Department cannot by administrative fiat overcome a legislative requirement. Clause 22 of the Approval therefore is an unreasonable and ultra vires condition imposed by the Department. Accordingly, Northern Pulp requests that Clause 22 of the Approval be removed entirely.

Northern Pulp hereby confirms that any documents submitted by Northern Pulp to the Department at any time, including but not limited to this Appeal and its enclosures, are being submitted with the expectation that the Department will observe the protections afforded to Northern Pulp by FOIPOP in respect of such documents.

CONCLUSION

In light of the above, Northern Pulp respectfully requests that you exercise your powers under Section 137(4) of the Act to allow Northern Pulp's Appeal and remove or revise the provisions of the Approval as outlined in this letter.

Yours truly,

Northern Pulp Nova Scotia Corporation

APPENDIX H-22

DILLON CONSULTING

NORTHERN PULP NOVA SCOTIA

Replacement Effluent Treatment Facility

Information Submission to CEAA

Internal Use Only

April 2018

4.1.3 Emissions, discharges and waste

Dewatered solids ('sludge') is collected as a waste material from the ETF. The sludge includes clay, sand, silt, organic matter, nutrients, microorganisms and metals. It is proposed that the sludge is mixed with the existing biomass feeding the NPNS Biomass Power Boiler. Combustion will occur as it does now, which is on a travelling grate at the bottom of the boiler, using the same controls and combustion temperatures as are currently being used. Quantity of sludge generated will be determined after detailed engineering is complete, but will be approximately 5 - 10% of the biomass currently fed to the boiler.

With the proposed future addition of sludge into the power boiler, potential for changes to air quality are being assessed using air dispersion modelling as part of the Environmental Assessment. Effluent quality is discussed under operation of the ETF in **Section 4.1.1** above.

The replacement ETF will significantly reduce odour emissions relative to existing conditions. Core to the treatment difference between the existing and proposed facility is how accumulated solids are handled. In the new system they will be continuously removed as underflow from the clarifiers. In the existing facility, solids settle over time in both the primary sedimentation basins and the aerated stabilization basin and decompose under anaerobic conditions, generating hydrogen sulfide, hence creating odour. Additionally, air needed in the process will be injected subsurface in the new facility. In the existing facility, aeration stages occur at the surface, by the action of the surface aerators that throw the effluent into the air to allow it to absorb oxygen. This action also allows sulphur compounds to be released to the atmosphere by volatilization. The new cooling stage was also designed with odour in mind. NPNS has opted to install indirect effluent cooling to completely eliminate any chance for odour release from this stage in the process.

4.2 Proposed in-Plant Upgrades

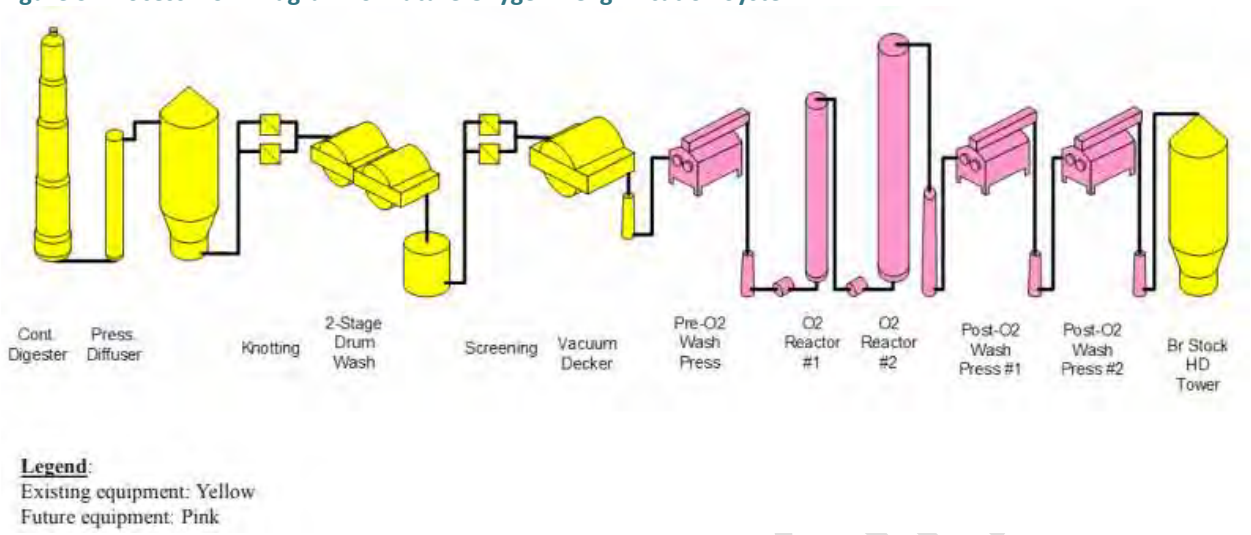
There are several in-plant upgrades proposed subsequent to the ETF project which are anticipated to further improve effluent quality, including the addition of an oxygen delignification system and fresh-water cooling towers. The environmental improvements resulting from the proposed upgrades described are not included as part of the EA. The proposed in plant upgrades will occur subsequent to the commissioning of the Effluent Treatment Facility, and therefore, the ETF must be able to meet approvals for construction without the upgrades in place.

4.2.1 Oxygen Delignification System

Two stage oxygen delignification technology will be incorporated into the pulp making process. The system includes oxygen reactors and wash presses. It will be installed after the brown stock washing stage and before the existing bleaching stages. A process flow diagram is included in **Figure 3** below.

Internal Use Only

Figure 3: Process Flow Diagram for Future Oxygen Delignification System



Oxygen delignification systems use oxygen gas to react with residual lignin that remains in the pulp after brown stock washing. The lignin removed in this new stage will result in the use of less bleaching chemicals to whiten the pulp in the existing bleach plant. It is a significant and well-proven process for Elemental-Chlorine-Free (ECF) pulp and as such it is often referred to as the first stage of bleaching (oxygen bleaching). Benefits of oxygen delignification include:

- Reduces chlorine dioxide bleaching chemicals by 30-40% leading to a decrease in effluent loading for BOD, COD and AOX;
- Improvement in aesthetics of effluent (colour);
- A reduction in wood losses;
- Increase in recovery of lignin that can be used in the boiler thus reducing carbon footprint; and
- A reduction in nutrients added to the effluent.

4.2.2 Water Cooling Towers

A significant portion of water consumption at the NPNS facility is using non-contact water systems for cooling and maintaining temperatures within the kraft pulp system. NPNS will install water cooling towers (subsequent to the ETF Project) to decrease the temperature of water used in the cooling systems. This will allow for water to be recycled within the system, as well as making the cooling itself more efficient. Water used in the cooling system, once too warm to be recycled, is fed into the effluent treatment facility. By making the cooling system more efficient, less volume of water in total will be used and ultimately less water will be transferred to the effluent treatment facility. The current cooling systems are once-through services with no segregation from the main effluent stream.

The water reduction as a result of the anticipated future cooling towers will be considered under the cumulative effects assessment in the EA.

Internal Use Only

Date: November 14, 2017 at 6:36:00 PM AST
To: "Martin, Frances R" <Frances.Martin@novascotia.ca>
Cc: "Fraser, Terri" [redacted]@northernpulp.com>
Subject: Phone call November 14 20(1)

During our telephone call today, you stated that your department is working on a response on my letter of November 3. I would like to clarify a few points:

Receiving Water Study and ETP Design
Your department has reviewed the Receiving Water Study (RWS) and have indicated that ENS is generally supportive of the concentrations used as inputs for the RWS and that these concentrations can be used as a basis for detailed design of the treatment plant. I would like to explain how those concentration inputs were derived. For normally regulated discharge limits (BOD, TSS and AOX), our consultants used the monthly limits as outlined in the Quebec regulations for existing pulp and paper mills. The Quebec regulations were reviewed in 2016. For effluent parameters that are generally not regulated, the consultants used the expected concentrations from the preliminary design. To recognize that there are daily variations in the operation, the Quebec regulations and most other regulations in Canada use the monthly limit and a multiplier to set daily limits.
Understanding that the EA outcome will be used to set the actual limits for a future IA, please confirm that the limits will allow for variations in daily operation as is the case in most regulations in Canada.

COD
We do not understand NSE's position on COD as outlined in the letter of October 5th. COD is normally not a regulated limit in North America. BOD is normally used to regulate oxygen demand in North America. Can you explain why COD is listed separately in the letter and why the concentrations listed do not match with those used in the RWS?

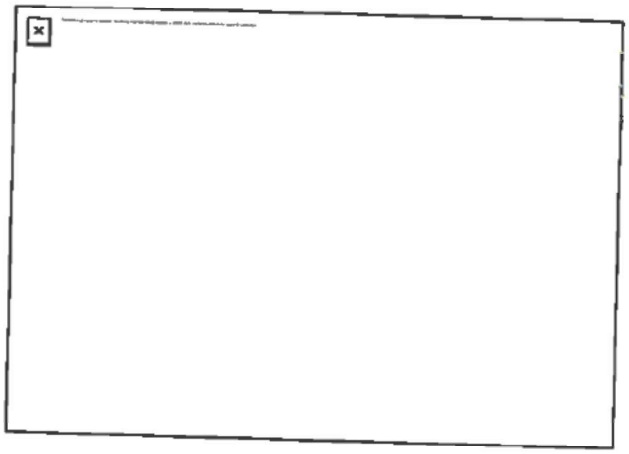
Water
NPNS understands that the we must continue to meet the current maximum daily water intake as outlined in the letter of October 5th.

Renewal of the Industrial Approval
As we discussed, regulatory certainty is important to the executives and the owners of PEC as the province and NPNS move forward on the Effluent Treatment Plant project. As such, NPNS would prefer for discussions on a future IA to begin as soon as possible. It is understood that there are many items in

Intended for Public Use

a future IA that will be determined by the EA process, so only items not associated with the EA will need to be discussed.

Is there a time tomorrow that you will be available for a short telephone call on these items?



Intended for Public Use

Northern Pulp Nova Scotia, Effluent Treatment Facility Replacement Project Update

Thank you for engaging with the Environmental Assessment (EA) study for Northern Pulp's replacement Effluent Treatment Facility. The feedback we receive during the EA study process will guide the environmental planning for the project.

A Class 1 EA process is being followed for this project. Nova Scotia Environment's (NSE) Environmental Assessment Branch determined that the project is a modification of an existing undertaking.

Engagement activities will continue to occur throughout the EA study. Our next steps are described below. At the completion of the EA study, the EA Registration Document is submitted to NSE for review. NSE's review process includes making the Registration Document available to the public and seeking public comment.

The proposed effluent treatment system is being designed to Pulp and Paper Effluent Regulations. Additional consideration of the Canadian Council of Ministers of Environment (CCME) Marine Guidelines and other national and international standards has been made. The design engineers, KSH Solutions with support from Stantec, used complex hydrodynamic models to develop the appropriate system to meet the guidelines. This replacement system is similar in design to many other North American and international Kraft pulp mills. KSH Solutions is a Canadian Engineering company with worldwide experience in the design of effluent treatment systems and has based their design on industry best practice to serve Northern Pulp's operations.

We are following up with key stakeholders and Pictou Landing First Nation for feedback on limitations and environmental conditions related to the outfall pipeline route and diffuser location.

The scientific modelling completed predicts there will be minimal impact on water quality in the Northumberland Strait, Pictou Harbour, Boat Harbour, and the near shore areas.

We have heard many questions related to the interaction of the treated effluent and the valued marine environment. Further studies to identify potential impacts and necessary mitigation measures will be completed.

Responses to Your Questions

Open Hause Format

Thank you for sharing feedback on how you found the Open House session. The format with the display panels allows for many voices to be heard through small groups or one-on-one conversations, facilitates a large number of participants, and respects different needs in communication. We will continue to try to create sessions where many people can engage in meaningful dialogue and consider this and other feedback received as we move forward.

Potential for Marine Enviranmental Impacts

The proposed effluent treatment system is designed to meet federal Pulp and Paper Effluent Regulations, similar to the existing effluent treatment system. Additional, more stringent, guidelines were also considered to achieve best practice in the design and operation of pulp and paper effluent treatment facilities. The development of monitoring programs will be an outcome of the regulatory process for approval of the facility. Under the Pulp and Paper Regulations, an Environmental Effects Monitoring Program is required. A copy of the Cycle 7 EEM report for the current treatment facility can be found on the project website. Additional monitoring programs will be designed based on approvals requirements.

i.e. monitoring won't be figured out until after approval

The Receiving Water Study, available on the project website, reports the modeled performance of how the treated effluent will mix into the Northumberland Strait through the outfall (the six port diffuser) and the resulting predicted water quality. One pipe will carry treated effluent from the treatment facility, located on the mill property, through Pictou Harbour to the outfall location. Six 'diffusers', or engineered outlets, will be installed at the end of the pipe. The Receiving Water Study also discusses how the diffuser design was determined.

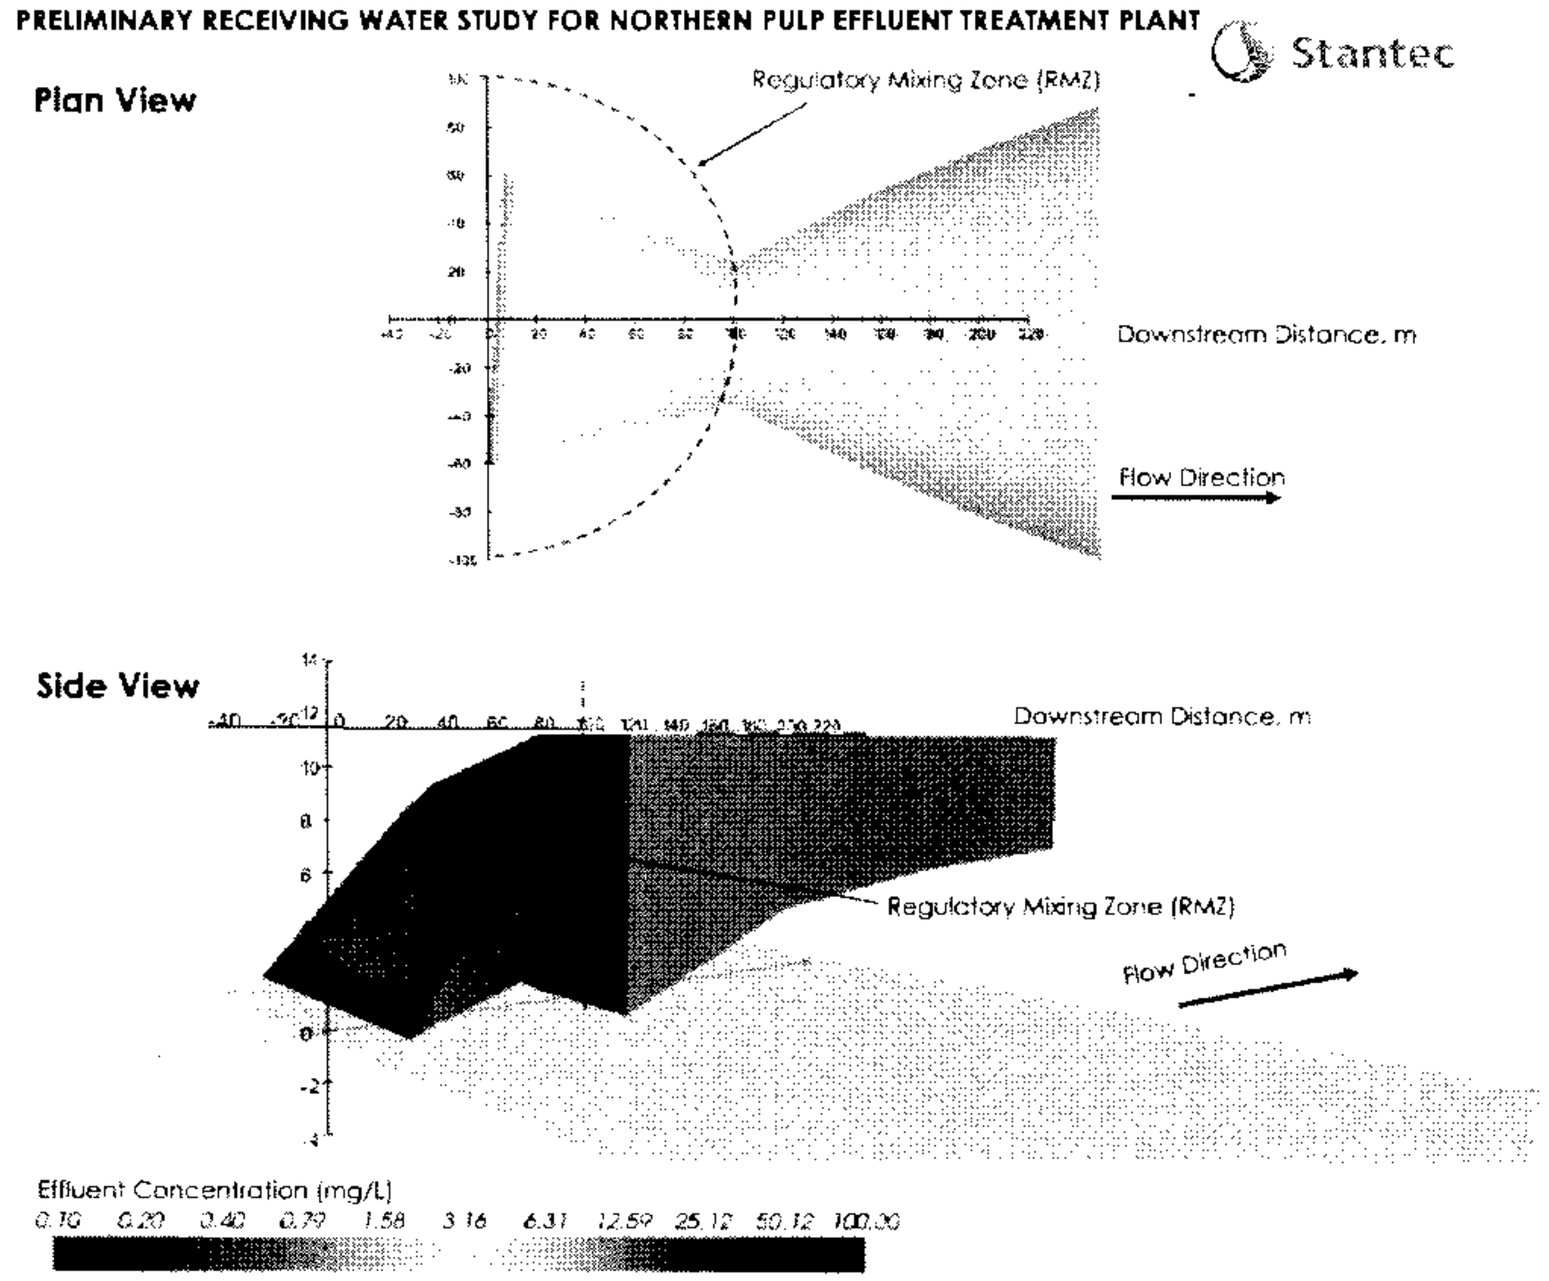
Available studies completed in the area will be reviewed, such as the Environmental Effects Monitoring of Northern Pulp, and the many studies being completed related to Boat Harbour.

The Mixing Zone

The water depth at the proposed location of the outfall pipe is 11.3 m (Mean Water Level). The mixing zone for the discharged effluent was defined as the lateral 100-m distance from the outfall following the Canadian Council of Ministers of the Environment (CCME) guidelines. To assess the impacts on the surrounding environment, be that lobsters at different life stages, or the plants on the bottom of the Strait which support the ecosystem, we must also understand where in the water column the mixing occurs. The effluent plume does not move upwards in a block, it expands from the diffusers upward but also laterally. Figure 3.7 of the Receiving Water Study, shown below, shows the shape of the effluent plume. The Receiving Water Study is available on the project website. The plume from the six port diffuser in the location chosen reaches the surface water at about 90 m from the diffuser. The dilution ratio in the receiving environment is 109 times at the end of the 100 m mixing zone as measured laterally from the point of discharge. Colour, for example, is

predicted to reach background levels within 40 m of the diffuser ports. At 40 m laterally from the diffuser, the effluent plume is still more than 1 m below the surface of the water.

Figure 3-7. Effluent Plume Scenario 6 - Six Ports Diffuser at Alt-D



Potential for Sediment Accumulation at the Outfall

The effluent is a liquid. Within the liquid will be an amount of 'suspended solids', similar to how silt can be suspended in a river. The amount of total suspended solids (TSS) discharged in the effluent in 2017 was 1,563 kg/day. By volume, this represents approximately 25 mg/L or 0.002S%.

The federal Pulp and Paper Effluent Regulations (PPER) manage threats to fish, fish habitat and human health from fish consumption by governing the deposit of deleterious substances from pulp and paper mills into waters frequented by fish for the protection of aquatic life. PPER specify a discharge limit of 11,500 kg/day for NPNS. The current discharge is significantly under the limit as significant improvements have been made over the years. The new ETF anticipates TSS discharges to remain low, in the range of 25 - 35 mg/L or 0.0025 - 0.0035%.

The solids which are present in the treated effluent will be very small particles left from the wood, and organics from the microorganisms used in the treatment process and are 98% biodegradable.

what are remaining 2%?

The Environmental Assessment (EA) will evaluate expected long term implications and potential environmental impacts related to the proposed replacement Effluent Treatment Facility. The replacement treatment facility design will incorporate the components needed to address regulations established with consideration of the longer term implications. As well, Environmental Effects Monitoring (EEM), which is a science-based performance measurement tool used to evaluate the adequacy of effluent regulations, will use baseline information to determine if any effects occur as a result of the TSS from the treated effluent discharge and to measure those effects, should they occur.

for where?

what about remediation?

Air Quality: Burning the Sludge

Being able to burn the sludge in the power boiler is the preferred approach as it increases power generation from green energy sources at Northern Pulp.

The dewatered solids include clay, sand, silt, organic matter, nutrients, microorganisms and metals. Sludge is typically either burned for fuel at treatment facilities, or used as soil or a soil additive as in all other Canadian provinces as well as in the USA, Europe, South America, Africa and Asia.

Changes to air quality will be assessed during the Environmental Assessment and will include alternative uses for the sludge.

Unrelated to the effluent treatment, Northern Pulp is separately addressing air quality concerns associated with its operations and working closely with the provincial government and regulatory authorities to continue to improve air quality.

Sharing Information

Results of specialist studies completed as part of the EA study will be made available upon their completion on the project website:
www.northernpulpeffluenttreatmentfacility.ca.

The study which looked at the initial siting of the outfall location and diffuser performance, and the study of treatment facility alternatives are posted on the project website now. Environmental monitoring (EEM) reporting of the existing Boat Harbour facility is also provided. The EEM is not directly applicable to the proposed replacement effluent treatment facility and the associated treatment effluent.

A "Frequently Asked Questions" list has also been added to the project website. Additions will be made to it as the project evolves.

Next Steps

Over the coming months, the project team will be continuing conversations with First Nations and key stakeholders, and completing environmental and engineering studies. Environmental plans to protect and/or mitigate potential impacts will be developed based on this information and input and dialogue.

In Spring 2018 we will return to the community with another series of Open House sessions which will provide answers to questions raised during the initial phase of engagement and present the recommended environmental plans and seek feedback.

If you have further questions or comments, please contact the project team at npns.effluenttreatmentfacility@dillon.ca, 1-877-635-8553 x 5050 and/or visit the project website www.northernpulpeffluenttreatmentfacility.ca.

Again, thank you for your time and interest. We look forward to continued engagement with you on this important project.

Sincerely,

APPENDIX H-25

July 9, 2018

@ns.sympatico.ca

Northern Pulp Nova Scotia, Effluent Treatment Facility Replacement Project Update

Thank you for continuing to engage with the Environmental Assessment (EA) study for Northern Pulp's replacement Effluent Treatment Facility. The feedback we receive during the EA study process is important and will continue to guide the environmental planning for the project.

Responses to Your Questions

On page 2.22 of Stantec's Receiving Water Study, it is stated: "Characteristics of the expected treated effluent from the NPNS mill for the new wastewater treatment plant were provided by KSH (KSH, 2016) as summarized in Table 2-6."
How did KSH determine these characteristics?
KSH determined the effluent characteristics identified in Table 2-6 from an evaluation and benchmarking of the NPNS operations and the predicted effluent quality that will result from changing from the ASB (Aerated Stabilization Basin) process to the AST (Activated Sludge Treatment) process for effluent treatment.

Are these characteristics expected after the oxygen delignification system is installed, or prior to its installation?
The results of the Receiving Water Study (RWS) do not account for the improvements that the Oxygen Delignification system will provide.

The RWS was conducted without considering the benefits of the Oxygen Delignification system. This way, the EA is assessing a conservative or 'worst case' scenario. A brief description of Oxygen Delignification and its environmental benefits are available on the project website*(*www.northernpulpfuture.ca*, Project overview drop down menu/in-mill improvements tab)*.

Will the oxygen delignification system be installed and operating when the AST system is in place, or is the plan to install the oxygen delignification sometime in the future, after the AST system is in place? If the oxygen delignification will not be installed at the same time as the AST system is in place, when will the oxygen delignification be installed?
The Oxygen Delignification Project will start-up after the new AST system is operational.

Sharing Information
In fall 2018 we will return to the community with another Open House session which will provide answers to questions raised during the initial phase of engagement and

APPENDIX H-26

Project Materials

Specialist Studies and Engagement Materials

Specialist Studies

Addendum Receiving Water Study for Outfall Location at Caribou Point

- During preliminary design, a discharge location for the marine outfall was selected in the Northumberland Strait as a preferred option. After subsequent marine geophysical and geotechnical field investigations, it was determined this outfall was not technically feasible. This addendum to the Receiving Water Study was completed to investigate two alternative outfall locations off of Caribou Point.

Brochure with information on the New Effluent Treatment Facility, Northern Pulp

- Brochure providing additional details on the new effluent treatment facility.

NPNS Global Market Study, Brian McClay & Associates Inc.

- The NPNS Global Market Study assesses the viability of converting the existing Pictou Northern Bleached Softwood Kraft (NBSK) mill to produce either Unbleached Kraft Pulp (UKP) or Bleached Chemi-Thermo-Mechanical Pulp (BCTMP). For the reasons outlined in the market report, it can be concluded that continuing to produce premium reinforcement NBSK is the most competitively viable option by far for Northern Pulp.

Receiving Water Study, Stantec Consulting Ltd.

- The Receiving Water Study was completed during preliminary design to (1) evaluate potential locations for a marine outfall and identified the recommended area, (2) evaluate and made recommendations for the design and performance of the diffuser at the end of the outfall, and (3) model how the treated effluent will mix with the water

at the end of the outfall, and (3) model how the treated effluent will mix with the water at the outlet in the Northumberland Strait.

2016 EEM Report, ECOMETRIX

- The Environmental Effects Monitoring (EEM) study gives the results of the environmental effects monitoring from the existing Boat Harbour Treatment Facility. This EEM study is not directly applicable to the proposed replacement effluent treatment facility and associated treated effluent, but was provided upon request.

Technology Selection Summary Report, KSH

- This report documents the Preliminary Engineering for which reviewed the technology alternatives when determining the approach for the treatment facility at Northern Pulp.

Middle River Water Availability Report

- Completed in 2015 by RV Anderson for the Government of Nova Scotia, this report reviewed the sustainability of the water intake used by Northern Pulp.

Engagement Materials

Materials used at project engagement meetings, and summaries of those meetings will be posted here. This way we will increase the transparency of our process, and allow as many people as possible to engage with the project.

(3) NOTE: Total reduced sulphur consists of 6 substances. Three of these substances (hydrogen sulphide [H2S], carbon disulphide [CS2] and carbonyl sulfide [COS]) are also listed individually in the NPRI substance list. If a facility meets the 10 tonne reporting threshold for any of H2S, CS2 or COS, it should report total reduced sulphur and the individual substance(s). Therefore, there is a potential for "double counting" of total reduced sulphur and the individual substance(s).

APPENDIX H-28

Project Materials

Specialist Studies and Engagement Materials

Brochure with information on the New Effluent Treatment Facility, Northern Pulp

- Brochure providing additional details on the new effluent treatment facility.

NPNS Global Market Study, Brian McClay & Associates Inc.

- The NPNS Global Market Study assesses the viability of converting the existing Pictou Northern Bleached Softwood Kraft (NBSK) mill to produce either Unbleached Kraft Pulp (UKP) or Bleached Chemi-Thermo-Mechanical Pulp (BCTMP). For the reasons outlined in the market report, it can be concluded that continuing to produce premium reinforcement NBSK is the most competitively viable option by far for Northern Pulp.

Receiving Water Study, Stantec Consulting Ltd.

- The Receiving Water Study was completed during preliminary design to (1) evaluate potential locations for a marine outfall and identified the recommended area, (2) evaluate and made recommendations for the design and performance of the diffuser at the end of the outfall, and (3) model how the treated effluent will mix with the water at the outlet in the Northumberland Strait.

2016 EEM Report, ECOMETRIX

- The Environmental Effects Monitoring (EEM) study gives the results of the environmental effects monitoring from the existing Boat Harbour Treatment Facility. This EEM study is not directly applicable to the proposed replacement effluent treatment facility and associated treated effluent, but was provided upon request.

Technology Selection Summary Report, KSH

- This report documents the Preliminary Engineering for which reviewed the technology alternatives when determining the approach for the treatment facility at Northern Pulp.

Middle River Water Availability Report

- Completed in 2015 by RV Anderson for the Government of Nova Scotia, this report reviewed the sustainability of the water intake used by Northern Pulp.

Engagement Materials

Materials used at project engagement meetings, and summaries of those meetings will be posted here. This way we will increase the transparency of our process, and allow as many people as possible to engage with the project.

Project Launch: Summary of Engagement - What We Heard

I am writing in support of the Environmental Assessment application submitted by Northern Pulp for its new treatment facility.

A lot has been said about Northern Pulp and its impact on the local community. I stand in agreement with many, including Unifor, that Boat Harbour must close and be cleaned up to respect Pictou Landing First Nations people and their land. I also know there are many positives about having 300 good-paying jobs in Pictou, supporting thousands more across Nova Scotia, particularly in rural communities.

The Nova Scotia Environment Act is an essential piece of legislation designed to protect our shared environment and guide our economic development. The Act rightly spells out its purpose through a set of principles for sustainable development that should guide its application, including:

------> The linkage between economic and environmental issues, recognizing that long-term economic prosperity depends upon sound environmental management and that effective environmental protection depends on a strong economy.

In this situation, science should determine the best path forward. Nova Scotia, along with the rest of Canada, has among the highest global standards for environmental stewardship in the forestry sector.

The job of government and every person we elect to represent us in government is to find the best way forward when there are many competing and sometimes opposing interests. Communities across Canada manage to find a fair balance where good mill jobs coexist with a prosperous fishing industry and thriving communities.

We can and must find this balance for Pictou. There is a lot at stake: jobs, the environment, and respect for First Nations. We can and must find a solution that supports all three.

Thank you.

In my option, everyone should be celebrating the incredible advancements being taken here to protect our environment. After the new effluent treatment facility is completed and the oxygen delignifacation process is added to the mixture, I think the owner will be leading the pulp and paper industry with remarkable numbers that will far exceed any standards set in the world. I'm also very pleased that the boat harbor clean up is coming in the future for everyone. I'm confident that there could be even more positive environmental tasks completed at the Northern Pulp site in the future, if we decide to work together with this valued employer in Nova Scotia today. We all want the same things, we all live here in Nova Scotia and the Northumberland Strait belongs to all of us and no one wants to hurt the Strait. My confidence comes from trusting the men and women that work in the Oceans and Fisheries Science Divisions of Canada, who are doing constant studies of our Strait everyday to ensure our ecosystem and environment is protected. Thank You for taking the time to read my option.

Thank you.

My parents owned at cottage that was located between Boat Harbour and Lighthouse Beach. We remained at the summer dwelling until . I was a teenager and I watched the water, and marine life change with the discharge . Nature was destoyed. Why can't this pulp mill and the government have a better solution for the waste , it is 2019 and not 1967.

Subject: NP Environmental Assessment Concerns
Date: March 8, 2019 7:22:32 PM

Dear Minister of Environment...and Protector of the Future for Young Nova Scotians:

While the latter might not be your "official title", it certainly describes the effects of your decisions and who they will actually impact the most.

I read through some of NP's Environmental Assessment and the biggest thing that jumped out at me, was that the assessment is incomplete! Throughout the document, Northern Pulp promises/assures that the effluent will not cause harm to the environment. On CBC, I listened to workers of the mill assure people and cameras, that "the effluent will be some of the best effluent in North America." However, in the company's environmental assessment, it states:

At this time, effluent chemistry characteristics (***including the specific substances present in treated effluent and their anticipated concentrations***) will not be known with certainty ***until the project is operational***. (p. 489)

I am an educator (currently living in born and raised in Pictou) and I always encourage my learners to "back-up" their answers. I want them to show me evidence of their thinking, and if we're talking science, I want to see results from experimentation.
It appears to me, this is a step that was missed out in Northern Pulp's Environmental Assessment! Where is the data saying what the effluent is made of? The science that shows exactly how it's going to be treated and its effects on the environment? And what about the lobster larvae tests that should have been done to reassure scared fishers that there is, in fact, nothing to worry about?!

Putting the pipe in the water and then waiting to see what happens, is not acceptable and it shouldn't be allowed - just based on the lack of effluent science alone!
In its 'uncertainties', this pipe would threaten and/or violate several of the United Nations Sustainable Development Goals - something that you wouldn't expect to see in First World Canada, but alas, here I am writing you this letter, hoping for an outcome that values:
Life on land;
Life under water;
Good health and well-being;
Clean water and sanitation;
Sustainable cities and communities;
Responsible consumption and production;
Climate action.

It doesn't seem worth it, to jeopardize all of the above, for an out-dated pulp mill that created the biggest case of environmental racism in the province. It's time we create opportunities for woodlot, sawmill owners and pulp mill employees to get together, be thinkers, and innovate for the future. I mean, how is Nova Scotia curbing the global

temperature rise of 1.5 degrees? Not putting in a pipe and shutting down a nasty precipitator would be one step in the right direction! :)

Please, please, please do right by Nova Scotians, our youth and our natural environment - no pipe in our Strait!

Kindest regards,

Subject:	Response to Northern Pulp"s EA Application
Date:	March 8, 2019 8:11:20 PM
Attachments:	NP EA comments.doc

Attached are the same comments that are in this email. I wasn't if there would be an issue with fomatting to I put it in both places.

Dear Premier Stephen McNeil and Minister for the Environment Margaret Miller,

I am writing in relation to Northern Pulp's Replacement Effluent Treatment Facility project.

My name is I grew up in Pictou, moved to Halifax in and then moved back home in I have followed and been very involved in most things related to Northern Pulp since 2013.

I know you are aware of the history of the pulp mill. I would like to use a brief summary of what I have witnessed as my preamble to why I oppose this project and will express my concerns. I feel their history is important and should be considered when trusting them with a project of this immense stature and historical significance.

Back in 2013, before Northern Pulp had their electrostatic precipitator installed, NP's emissions amounted for 63% of all particulate matter released in the province. They were allowed to exceed limits because a ministerial order allowed them to do so while they were working towards compliance. People in the area including area doctors and the Nova Scotia Lung Association complained that this was not acceptable. Northern Pulp's response was 'give us a chance, we need more time'. While their recovery boiler was failing stack tests, so were the stack tests for their power boiler. The following year they upped their emissions to 78% of what was being released in the province while hitting production records. That was the year of the pipe leak.

In June 2014, Northern Pulp had a leak in their effluent pipe that took a couple of weeks to clean up (1). When the numbers were initially released we were told that there was 4-5 million litres that had spilled onto Mi'kmaq burial grounds and into the Northumberland Strait. Through the federal investigation, it turned out to be 47 million litres. Northern Pulp's negligence to properly maintain this pipe lead to the Boat Harbour Act. Without the Act, Northern Pulp would likely have had to close. The closure date was set for Jan 31, 2020 and mill officials said they would honour the act and honour the closure date although they admitted that they found the date rather tight.

With their next Industrial Approval looming, NSE set water reduction targets. Once the approval was put forward, Northern Pulp threatened to sue the government over the reduction targets. The govt eventually allowed for higher reduction targets. Northern Pulp has cited this litigation for being a reason for their late start despite the fact that they knew they couldn't operate without a new ETF to replace Boat Harbour and that they felt there was a time crunch. That is admission that NP chose not to start working on their ETF right away creating more of a time crunch.

After having the new precipitator installed, Northern Pulp were still failing their stack tests routinely on their power boiler. They no longer had to report the results and the only way to find the results were through Northern Pulp's Community Liaison Committee. When I contacted , NP and Paper Excellence's Communications Director, said that I couldn't talk directly to the CLC. I had to ask questions, would relay them to the CLC, they would respond to and would relay that back to me. Checking on each stack test after this, the response that I got on everyone from was that they were passing. They were not (2). This resulted in a fine for $697.50 and a directive that the company had to reveal their test results.

During this time, they could have filed for their EA submission but according to a recent FOIPOP they were busy demanding a 10 year Industrial Approval, despite not having gone one year without failing to meet at least one term of their Approvals and demanding that an increase in their water usage stating that they wouldn't go forward with their EA as these terms didn't work for them. Another indication that the time crunch was brought on by themselves. All along officials for the mill continued to state that they would honour the closure date.

Another recurring theme that has been presented by the mill is that the effluent will be cleaner than what comes out of Boat Harbour. According to recent FOIPOP, Northern Pulp's technical engineer admitted that the new effluent will be worse that the present effluent.

They finally announced open house dates to educate the public on their ETF plan. They put forward a plan that included a pipe that would go through the Pictou Harbour and have an outflow location in shallow waters with 6 ports spread over a distance of 125 metres in order to bring readings to background levels within 100 metres. They also showed in schematics an Oxygen Delignification system that one of their reps said would be crucial to the process at a cost of $70M that would be completely funded by the Mill owners. Concerns that were raised that night included a very well publicised shipwreck that had been found and mapped in 2015 (3), the shallow waters of the area that would cause ice scouring and requiring 125 metres of release from start to finish to reach background levels within 100 metres. KSH consultants also seemed unaware that fishing took place in the area where the outflow pipe was to be located.

FOIPOPPED information showed that by May 2018, Northern Pulp knew this plan would fail because of the shipwreck and ice scouring. This is just speculation but it seems being that this information was readily available that there was a planned failure to create even more of a time crunch. In July, they said they would file an EA submission on their ETF in the fall while admitting they knew the shipwreck was there all along (4).

Early in 2018 there was an ash spill resulted from a pipe leading to the power boiler that received an environmental directive. The big news on pipe leaks came on Northern Pulp pipe leaks came in October when NP had another large raw effluent leak that took more than two weeks to clean up. The amount is currently not known to the public because it is currently under investigation. A key point to note with this is the manner in which the leak was found. The mishap was discovered by someone randomly walking

their dog through the woods. This is very similar to how the 47 million litre leak that precipitated the Boat Harbour Act and brought assurances from the mill that this would not happen again(5).

Northern Pulp didn't plan for new survey work for Caribou Harbour to take place until the end of October into November. Adding this new component by not starting the survey work so late would have resulted in NP not being able to submit until January 2019 at the earliest. The fishers and the First Nations blockaded work against the surveryors. Despite all of the delays that NP created for themselves and their filing in January 2019 which followed a time line that, as stated, they created, they blamed the fishers blockade as a major reason for the delays.

After years of saying that Northern Pulp would honour the Boat Harbour Act, announced on Jan 31, 2019, along with their EA submission, that they would seek an extension on the use of Boat Harbour indefinitely while also stating that the continued sad history between the Mill, the Pictou Landings First Nations and Boat Harbour could no longer continue (6). A statement that completely contradicts itself. To add to that she stated that the Pictou Landings First Nations and Northern Pulp had shared goals. This announcement was made on the day the PLFN were celebrating that Boat Harbour would finally be able to be returned to what it was before it was stripped from them five decades ago. Despite the Boat Harbour Act negotiated by the NS govt and the PLFN that five years before gave Northern Pulp a fighting chance at continuing while clearing the way for Boat Harbour remediation, Northern Pulp and the PLFN clearly don't have shared goals anymore.

From a personal perspective of this process, a couple of the questions that I submitted to Dillon Consulting were "What is the effect this effluent will have on lobster?" and "Will there be testing done with the proposed effluent on lobster." In the EA there is a section that lists questions that the public submitted. Those questions don't appear there. In fact, there is not one reference to studies done on lobster in the entire EA because they never completed any.

My concerns with Northern Pulp's EA submission for their ETF broken down into sections:

1) The process

2) The pipeline route

3) The outflow location and plan

4) air emissions

5) ETF location

6) Integrity of the proponent, ability to comply with the Industrial Approval

7) Impacts on Fishing and Economic reasons

8) municipal laws and other factors

1) The Process

A class one assessment was chosen for this project. According to then Minister for the Environment Iain Rankin that classification was automatic (7). Looking at Nova Scotia's guidelines on classifications of environmental assessments, a class two definition is described as "undertakings are typically larger in scale and are considered to have the potential to cause significant environmental impacts and concern for the public... These undertakings require an environmental assessment report and formal public review which may include hearings." (8)

Northern Pulp's submission is approximately 1700 pages for an ETF that will cost about $130M of taxpayer money IF the court case between the province and Northern Pulp against the First Nations reverses a decision that found that the province had to consult with the First Nations before money could be handed to Northern Pulp. This project will have lasting affects on both the forestry and the fishing industry for decades to come. That should be by definition 'larger scale'. There have been Class two assessments for projects in this province before. To get a better understanding of perspective on the Class one decision, where does the government see Northern Pulp's ETF submission in relation to those other projects and what were those other projects that warranted more scrutiny in terms of scale?

A plan with the capacity to pump up to 85 million litres of effluent into prime breeding grounds of the Northumberland Strait not only will cause a significant environmental impact but also has drawn a large concern for the public. The Land and Sea rally brought over 3000 people and 200 Boats to Pictou for a protest (9). Thousands of letters representing First Nations, Fishers, Citizens, Tourism and Fishing Associations from 3 provinces and 19 Federal Senators have been sent to the federal government asking for a federal assessment. This demonstrates 'concern for the public'.

Mr. Rankin's decision on the project warranting a Class one assessment can still be properly applied when present Minister for the Environment Margaret Miller conducts her review. The details of the project, possibly being larger than Mr. Rankin expected when he made his decision, can still face proper scrutiny under a class one as there is a caveat that allows "Other opportunities may exist if the Minister decides that a focus report or an environmental assessment report is required" (8) Barring either the submission being denied or an about face to allow for a Class two assessment, it would seem that adding the focus report or environmental assessment report would be the logical next step.

In Northern Pulp's EA submission they explain the process of informing the public. This included open houses, mail outs, press releases and the like. A major concern here is their original presentations reached a lot of people with details that are no longer part of their plan and the change in outflow location changes the amount of concern some people would have for the project. When the original open houses were conducted, the plan was to pump effluent to the mouth of Pictou Harbour. People who live in the Caribou area may not have been as concerned or followed the plan as the outflow wasn't going to be close to their property. With a submission of a 1700 page document, someone finding out about this large scale project would not have the time to decipher such an immense technical document in 30 days. Even on a recent episode of "The National" CBC had a graphic showing the proposed pipe going out through the mouth of Pictou Harbour instead of the submitted plan for the pipe going out Caribou Harbour (10). Northern Pulp's website that was set up to educate the public still has a lot information that is now incorrect due to their change in plans (11). Northern Pulp also set up a facebook group requesting that people have an open mind and ask questions. Shortly after that, they banned a lot of people who were asking questions and routinely delete comments of concern. Due to the level of effort made by Northern

Pulp to educate people on their original plan, there should have to be at least equal effort for Northern Pulp to consult and educate the public on their actual submission to ensure the public actually understands what NP plans to do and not rely on what NP had originally told them their plan was.

To this date, Northern Pulp still has not held an open house in the Town of Pictou even though their original plan was to have the outflow point at the mouth of the Pictou Harbour or with their submitted plan that has raised concerns over the plan to due work over and put an effluent pipe through the town's watershed.

During the original open houses, Chief Andrea Paul pointed out that there wasn't an open house scheduled in Pictou Landing. Northern Pulp agreed and after word got out, tried to discourage people who weren't from the PLFN from attending. Chief Paul correct that stating that anyone wanting to understand this project were welcome to attend.

There is a lot of concern over the perceived conflict of interest around the NS govt role in making a decision on NP's ETF approval with the indemnity agreement (12) possibly influencing Nova Scotia's decision in that the province could be financially motivated to find in favour of the proponent to avoid litigation. This was one of the reasons for requesting a Federal Assessment.

2) The pipe route.

The plan submitted has the pipe's route to go along the Harvey A Veinot Causeway, over Pictou's watershed along the Trans Canada Highway and out 4kms into the Northumberland Strait.

On page 11 it is explained that "An EA identifies potential environmental affects, proposes measure to mitigate adverse environmental effects, predicts whether there will be significant adverse environmental affects after mitigation measures are implemented, and includes a follow up program to verify the accuracy of the EA and/or the affects of the mitigation measures."

Early in the submission on page 12, it states that NP did not "facilitate full biological field assessments for the current proposed transmission pipeline corridor". It goes on to state that this nor studies on the marine environment weren't completed in time for their registration. Their 'commitment' to follow up shows that they recognize that this work is important to their submission. It continues on page 13 to say this work will be done in the spring and summer. If it's important to the submission, then it should have been completed and included in the submission. How can the quote in the previous paragraph be followed if studies have not been completed?

One of the first issue with the pipe route has to do with migratory birds. In the EA submission, it says that there is non significant affects on migratory builds yet from late April until early October, cormorants make the side of the Causeway their home. There is nothing in the EA that addresses this. Any construction of a pipeline would damage where they live and do them significant harm. This shows just one of the many potential omissions with relying on desktop studies instead of doing the actual work.

After you get across the causeway, you are moving the pipe across the town of Pictou's watershed. The construction of and the use of an effluent pipeline puts Pictou's source of water at risk. The town is in the process of its own major project to finally secure drinkable water for the citizens who have not been able to have drinkable water. Whether the risk arises during the construction or 50 years down the road, as mentioned in my opening preamble, Northern Pulp does not have a demonstrated history of showing either proper maintenance of pipelines nor monitoring for when damage of pipelines arise. This is a risk that is not worth taking.

The pipe then moves along the shoulder of the Trans Canada Highway near water courses and wetlands on its way towards where it reaches the Northumberland Strait. The aforementioned lack of studies on biological and marine environments and Northern Pulp's previously mentioned history is cause for concern here as well. With their not having done the studies and no plans to have them completed until the summer, I don't see how the NS Department of Environment can even make a judgement on the potential risk for this area.

<!--[if !supportLineBreakNewLine]-->
<!--[endif]-->

3) The effluent pipe's outflow location and plan

The plan is to extend the pipe about 4 kms from the shore through Caribou Harbour to an outflow location that appears to have a debth of about 40-65 feet made of mud, sand and rock (13). To put this depth into perspective, 60 feet 6 inches is the distance from home plate to pitchers mound on a baseball field. That's deeper than the original outflow point near Pictou Road but still not very deep. This is adjacent to the PEI ferry route and requires routine dredging do to shifting sand and silt. Dredging generally seems to be done approximately every 10 years (14). The end of the pipe itself will have three ports with a plan of dispersing the effluent, that as described by NP's technical engineer in the preamble, will be worse than what is coming out of Boat Harbour now. In the EA it states that the characteristic of the effluent will not be known until project completion. They know it will be worse, but don't know how bad and can't submit a testimony to that quality in time for NSE to make a ruling on whether it is okay for an ETF with a capability of producing up to 85 million litres of that unknown effluent each and every day.

The original plan called for six ports being required for the dispersal. The present plan calls for three ports. This is one of those facts that anyone going by Northern Pulp's open houses and distributed material are not aware. Under ideal conditions, this is supposed to bring the effluent to background conditions within 100 metres to meet Federal Guidelines. Although this trench is deeper than the original outflow location it is a narrow trench with a shifting bottom. It is also a very important area for among other like lobster, crab and herring, it also includes species of concern like Atlantic Salmon and Stripe Bass. Northern Pulp and their consultants/contractors have not completed the survey work for the area yet somehow concluded that there will be no adverse affects.

Concerns with this location that are not known include the affects that the shifting bottom will cause, the ability for the outflow pipe to remain free of mud and silt and the extent and characteristic of monitoring to ensure there are no issues. Monitoring on other components of NP's Industrial Approval are infrequent and lack any consequences that would motivate concern from NP. The indemnity agreement absolves the mill and its successors from harm. The province owns the effluent.

According to the EA, the effuent will contain 4,000 kg total suspended solids each day.

This would add to the build up that would end up in this narrow channel that is only about 60 feet deep.

Ice scouring was a major factor that prevented the first plan from working. Ice scouring and ice build up is an occurrence throughout the Northumberland Strait. Stantec's research has shown there to have been 133 features during their 2015 survey that was completed for the PEI-New Brunswick cable interconnection upgrade project (15). Just to reiterate the point, Northern Pulp have not completed their assessments on this and again have concluded there will be no adverse affects.

Page 21 of the EA shows that assessments by NP need to be completed for DFO in relation to fish habitats. "Geotechnical investigation will be completed inorder to facilitate detailed design and provide sufficient information to estimate the harbour/marine footprint of the pipeline/outfall. Habitat assessment and preliminary proposed project footpring infomration will form a component of a DFO Request for Review to determine authorization requirements under the Federal Fisheries Act." If this study hasn't been done and DFO can't authorize the pipe due to concern over potential serious harm to fish, the province shouldn't be able to authorize the project as Northern Pulp wouldn't have been able to show that it would be operational before the decision by the Minister for the Environment is made.

According to CLC meeting minutes from Spring 2017, Northern Pulp required both the Boat Harbour ETF and the New ETF to run concurrently for six months while the biology developed in the AST system (B). According to page 81 of the EA, the commissioning phase would take between one and three months. This is concerning because it sounds like the timeline is being rushed to compensate for money that could be lost should the appropriate time be taken for the biology to develop.

4) Air emissions.

There's a section in the EA that addresses VOCs on page 141. In it Northern Pulp tried to discredit the findings that showed we have elevated levels of VOCs while trying to pass the blame off on a combination of Michelin and NSP Trenton. I found it interesting that the EA found it not credible because the study to which they referred went with "a statistical evaluation of ambient data in correlation with wind direction, without further site specific investigation" yet the EA surmised that the VOCs may have come from other sources like "transportation sources, or other industrial sources like the Michelin Tire plant or the Trenton coal-fired power plant, **presumably** all sources of VOC emissions to some degree." The EA also stated that VOCs had elevated levels when the prevailing winds were from the northeast of the mill. Given the locations of Michelin (to the west) and NSP Trenton (to the south) it would seem that there must be more validity to the data collected in the paper by Hoffman et al. then the 'presumption' that this EA submission is making. At the very least, it strengthens a case for having continual emissions monitors on not only Northern Pulp's stacks but possibly those of Michelin and NSP Trenton as opposed to making presumptions and allowing elevated levels of VOCs to continue based on the failed logic that, since you can't tell whether it's one or all three of the main sources of air pollution in the county, it doesn't require further investigation.

Emma Hoffman recently defended Northern Pulp's presumptions in a recent article for The Examiner. (A) " Northern Pulp's EA also stated that the study did not attempt to rule out the contributions of other potential sources. But Hoffman, Guernsey, and Walker say this "is clearly not a true statement," and that the study did not disregard other potential sources of VOC emissions. The study openly acknowledged and discussed in detail the other potential local emission sources in the area, including a coal-fired generating station in Trenton and a tire manufacturing facility. The study even provided a map indicating these other potential sources relative to the Granton NAPS site." Just because Northern Pulp states something, doesn't mean it's true.

With the new ETF, sludge is to be dewatered and burned in the power boiler. This will cause an increase of about 5% more pollutants in coming from the power boiler. Northern Pulp has only managed to stay under the emissions limits as lain out in their Industrial Approval for just over a year now which only spans six tests. Again, a change like this with a company that has a reputation for failing its emissions tests would warrant Continuous Emissions Monitoring system in place. Page 148 even has Northern Pulp stating that they believe there should not be increased monitoring despite the adding of a new element to what they are burning in their power boiler. This demonstrates that they don't want more scrutiny on part of their process that has failed in the recent past.

The EA states that they won't know the effluent's chemical makeup until after the project is complete. If that is the case, how can they know the chemical makeup of the sludge that they plan to burn in their power boiler? What will that chemical makeup be once it becomes airborne? How will that increase the level of VOCs in the area?

During the open houses a key component that also appears pictured in the EA submission is the Oxygen Delignification system. Consultants said that this would cost about $70M and be paid for by the mill owners. In the EA it is highlighted in a different colour and it says that it would be built in the future. If this is a key part of the operation to reduce emissions, smell and make the effluent better (which as we covered before, is actually going to be worse) why is it not part of this project? With the length of time it is taking Northern Pulp to get this $130M project underway where they may not even have to foot the bill, I am concerned that this promised oxygen delignification system will not come to fruition.

5) ETF Location

The plan is to locate the ETF next to where Canso Chemicals was/is. Knowing the history of the missing mercury, what sort of excavating/site cleaning will go on here? I have concerns over any chemical from or near the former site being unearthed. Who would over see this work? I would expect it would be some third party agency like NS Lands who have experience with this sort of work. What would be the process for doing any of the clearing? Knowing the concerns facing the removal and disposing of anything on the mill property or on the property of Canso Chemical be treated with the same care that is being applied to Boat Harbour which received both a Class Two provincial assessment as well as a Federal Assessment? If not, why not?

I did not find a mention of mercury in Northern Pulp's EA submission and considering the history that the two properties share, that should have been given consideration and seems perplexing with its absence. Is there any chance if this place isn't excavated properly, that any mercury that is on site could seep into the sludge and end up burned in the power boiler?

Are Canso Chemicals, it's current or previous owners protected by the Indemnity Agreement? Are people who are connected to Canso Chemicals that are also connected to the mill held free of harm should any wrongdoing be uncovered that relates to their connection to Canso Chemicals?

6) Integrity of the proponent, ability to comply with the Industrial Approval

Any decision to grant an approval on a project like NP's ETF should take into consideration the people in charge of the work and overseeing its operation. If I were to submit this identical proposal, I wouldn't expect NSE to grant my approval because I have not demonstrated the capabilities of completing a project of this size.

Northern Pulp has had about a dozen infractions, ministerial orders and pipe leaks. They are on Canada's Environmental Offenders registry. They are currently still under investigation for their most recent pipe leak. I realize the timing of Northern Pulp's EA submission and the 30 day public consult period followed by the 20 days to make a decision period was not precipitated by actions of the Minister for the Environment or NSE. Making a decision on granting a project of this magnitude prior to completing an investigation for an event that could lead to criminal charges just doesn't sound prudent. It feels akin to making a decision to leave your child with a babysitter this weekend even though you know a decision on child abuse charges for that babysitter will be announced the following Monday.

Any approval for this project hands over responsibility for monitoring and maintaining operations this project to a proponent with a horrible track record who has stated in a number of spots in this EA that studies that it agrees should be done, have not been completed.

Northern Pulp, as explained in my preamble, have a demonstrated history of saying one thing and doing something different. Examples previously given and cited include failure to do proper maintenance and monitoring of an effluent pipe.

Concerning is the combination of lax regulations, lack of monitoring and weak enforcement and penalties that was cited by the auditor general (16) not only in general in this province but how that applies to Northern Pulp. During the installation of the precipitator, NP was allowed to keep operating because it was "working towards compliance". That took a few years. That is not acceptable. When talking about an effluent pipe that could put the ecology of the Northumberland Strait and its corollary fishing industry at risk, allowing a mistake to continue for years while working towards compliance is not an acceptable option. If there is a malfunction that is noticed, what steps are going to be taken to properly empty the 15km pipe before its contents are pumped out into the Northumberland Strait?

7) Impacts on Fishing and the Economy

One of the big rallying cries from Northern Pulp has been what the closure of Northern Pulp will do to jobs in the province. Stepping away from the very real fact that the dilemma of Northern Pulp closure has been brought on by their neglect of their effluent pipe followed by their not coming up with a suitable replacement plan for the Boat Harbour ETF, jobs are important. What seems to get lost in all of this is the fact that fishing and tourism jobs matter as well. Those industries are not doing anything to put Northern Pulp's business in peril. Northern Pulp did that to themselves.

There are about 300 people who work for Northern Pulp. Their economic activity accounts for 5 indirect jobs for everyone direct job so a total of about 1800 jobs. There are over 3000 fishermen who work in the Strait. Applying that same metric would mean 18,000 jobs would be at risk if we kill the Northumberland Strait fishing industry. Tourism was not even considering in Northern Pulp's submission.

In 2003 Alberta had a case of mad cow disease (17). This was estimated to have caused a $5B hit to beef producers. Stewardship over fishing happens in much the same way. If one lobster is contaminated, just like the Alberta mad cow incident, hamper the Atlantic region's ability to sell seafood. It took about two years before Alberta was allowed to resume business as usual. It took remedying the situation and reassuring the markets Alberta beef was safe to eat. Those factors would not be in play with Atlantic seafood because we likely would still be pumping the effluent that caused the problem each and every day over that two year period and continue until the end of the life of the mill.

Northern Pulp exported about $220M in product in 2017. Fishing topped $2B last year in exports. Tourism on the North Shore topped $200M with the NS economy growing by about a half billion in the last few years to the $2.7B mark (18). The Ivany Report set a goal of expanding tourism to $4B. Nova Scotia's brand is the based on the lobster and being Canada's Ocean Playground. We have the warmest waters north of the Carolinas due to the Northumberland Strait being shallow and warming quickly in the summer. If we develop a reputation sick lobster and unswimmable waters, there goes fishing and tourism.

On page 110 of the EA, Northern Pulp draws the conclusion that there will be no harm to the commercial fishing industry without doing any tests on fish.

8) Municipal laws, PLFN and other factors

Currently, Northern Pulp does not have permits for running a pipe through the town of Pictou or the County of Pictou. I do not believe a project should be given the ok until these can be obtained.

At the start of this process we've heard repeatedly about the indemnity agreement, Nova Scotia taxpayers being on the hook for costs and negotiations being ongoing when it comes to who is paying for the ETF project. In the fall, a Supreme Court decision came forward that the province would have to consult with the PLFN on any funding that would go to Northern Pulp (20). Northern Pulp has recently joined the province in its fight against that decision although the current situation is that Northern Pulp will not get money from the province to pay for this ETF project. Being the current situation, Northern Pulp should not be allowed to move forward on this project without showing that they would completely fund this project.

At least fifteen First Nations fishermen, fish out of the area of the outflow pipe. "The Supreme Court of Canada confirmed that the Mi'kmaq and Maliseet First Nations continue to have treaty rights to hunt, fish and gather towards earning a moderate livelihood. These Treaty rights must be implemented. Along with these treaty rights, First Nations maintain that they continue to hold Aboriginal rights and title throughout their traditional territory. This creates a special situation unlike any other found in Canada. There is no model or generic approach to follow on how to prceed in these gegotiations. All parties must be prepared to consider how to devise a negotiation process which meets everyone's circumstances, needs and interests." (21) This would seem to indicate that if the Mi'kmaq of the Pictou Landings First Nations are not in agreement with risking their ability to fish in a this area where they hold Aboriginal rights and title, then the NS govt can't approve this project.

My understanding of the Boat Harbour extension that was signed by then Premier John Hamm may not have been legal and faces future legal challenges. I believe that should be dealt with before any 'compensation' on ending the Boat Harbour lease before 2030 should be given.

On page 70 Section 5.2.1 it says that Northern Pulp will be in charge of monitoring effluent quality discharged to the receiving environment. They are supposed to be in charge of that now and that has lead to two large raw effluent leaks in less than five years. I believe they've demonstrated an inability to complete these tasks.

Page 82 lists a number of things that Northern Pulp should have completed before filing let alone obtaining approval. They include: various approvals, avian/turtle studies, MEKS field studies, Archaeological shovel testing for pipeline, geotechnical land surveys for land portion of pipeline, marine seismic testing, habitat and confirmation of marine pipeline alignment. Still no mention of testing effluent on creatures like lobster, crab, Atlantic Salmon, striped bass...

I do not believe the effluent test of putting ten trout in a bucket of effluent for 96 hours to see if more than half survive could ever be described as adequate testing regulations to meet effluent quality. Throwing that kind of testing at the our fishing industry is plotting a course for disaster.

On page 106 of the EA, NP states that neither the Fishermen nor the PLFN offered any input to the outflow location evaluation other than expressed opposition. This seems to try to discount their opposition to a pipe going into the Northumberland Strait as the Fishers and the PLFN not helping with the decision. At the open houses, NP was told by the fishers and PLFN that the water was too shallow and there would be ice scouring. The prevalence of ice at the Caribou Harbour location would not be much different. Either way, a plan that would put their fishing livelihood at risk was not going to be

acceptable. The fishers' associations even offered to help cost share any project that didn't involve putting a pipe into the Northumberland Strait. Basically, this amounted to the fishers and PLFN evaluating the plan based on their vast knowledge of the Northumberland Strait as a bad idea and Northern Pulp disagreed based on their wanting to put a pipe in the Strait.

My Conclusions.

I believe the repeated mentions of studies that have not been concluded demonstrates that the proponent has still not completed all of the work necessary for this to have been submitted in the first place. Seeing their comment that the AST system could be brought up to speed in 1-3 months after telling their CLC that it would take six months adds concern that this project is being rushed and proper care is not taking place. Changing the outflow location doesn't really change the concern of ice scouring that caused their first option to fail.

From a purely environmental side of things, having effluent that is worse than what is going into Boat Harbour and pumping that into the prime breeding grounds of the Northumberland Strait seems completely ill-fated considering what the current process has done to Boat Harbour. At least with Boat Harbour, most of the damage was contained to the receiving basin, Boat Harbour and the shoreline.

From a legacy point of view, look at what the legacy of the decision to strip Boat Harbour away from the Pictou Landings First Nations has created. It's one of the worst cases of environmental racism this country has seen. Pumping this effluent into the Strait has the very real potential of poisoning our water and our food. I know not being able to prevent the disaster that became Boat Harbour weighed heavily on the PLFN. I can't imagine what making a similar decision with the potential for similar consequences on behalf of everyone would be the legacy I'd want to leave to our children.

From a point of having faith in the people running the mill, I don't understand how they could have a new Industrial Approval approved. About a dozen infractions, ministerial orders and pipe leaks. At some point they should be held accountable for not meeting the terms of their approval or what is the point of issuing terms with an approval?

If the decision is being weighed as a protector of jobs or from a purely economical stance, there's more at risk with harming our fishing industry. If that pipe goes in, we're likely locked into the ramifications of living with a bad decision if things don't go well for the next 50 years with a pulp mill that will be over 100 years old.

There really hasn't been an effort made to come to a reasonable agreement with the Fishers or the First Nations. Throughout the process it has been Northern Pulp dictating what they want to do with their tag line 'no pipe = no mill'. That really causes concern in that it wouldn't be surprising if instead of trying to come up with a plan that works, this process feels like it was 'this is the plan', now how do we dress it up to look like it works.

Northern Pulp have stated that they require an extension on their use of Boat Harbour. As outlined early on in this, they've had over five years and chose initially to take other actions instead of getting the ball rolling. This latest ask for more time is far from being their first ask. The mill has been failing since they took it over and we've been hearing the phrase 'we need more time, just give us a chance' since the beginning of their ownership. The mill was designed to last 25 years and was 40 years old. According to Lana Payne from Unifor, the concessions made in their contract were to allow the owners to renovate the mill because proper upkeep hadn't gone on in 40 years. If the decision were made to okay this new ETF, when would the province be buying a new mill because it feels like we're putting brand new tires on a car that won't last the week.

Please see the EA submission as the large incomplete document that it is. At the very least, the immense size of this project, the material put forth, the potential risk to the environment and the large amount of concern that people have for the risk to their health, the environment and their livelihoods, if this EA submission isn't rejected, it definitely warrants a focus report (environmental assessment report).

Thanks for taking the time to read this. Making a decision on this, even if the choice is clear, is not an easy task.

Re: Northern Pulp's Replacement Effluent Treatment Facility

Dear Madam Minister:

I am a resident of Pictou County on land that borders on the eastern end of Caribou Harbour. My family and I regularly walk and swim at the beach that is part of the Caribou Provincial Park. We bird watch on Munroe's Island. We regularly kayak and sail the waters of Caribou Harbour. I have accompanied fishers as they pull lobster traps off of Caribou Point and hunt for herring off of Pictou Island.

I am also a Professor of Fine Art at York University in Toronto and a professional artist. I have produced several works based on my research and experience of Caribou Harbour. These can be found at the following web addresses: http://memoryfactory.sitemedia.ca and http://www.cariboumottos.ca

I am writing in response to Northern Pulp's submission of its plan for a replacement effluent treatment facility and the proposal to place an effluent pipe not far off of Caribou Point into the waters of the Northumberland Straight.

Caribou Harbour is a unique estuarial environment that has been a source of food and therefore human culture for hundreds, if not thousands of years. It is a significant part of Pictou County's Northumberland Coast, its history and cultural identity. It is also a highly changeable body of water subject to tides, ice, fierce storm surges and fluctuating temperatures. Caribou Harbour is shallow and prone to silting to the degree that access to fishing wharves requires occasional dredging.

Our website www.memoryfactory.ca referenced above is dedicated to local memories of the Maritime Packer's plant at the east end of Caribou Harbour, adjacent to the Little Entrance, a channel through the isthmus between the mainland and Munroe's Island. The Little Entrance provided a safe harbour and immediate access to the rich fishing grounds between Caribou and Pictou Island. Maritime Packers for many years was the largest lobster processing plant in the area, some say the world.

In the mid 1980's the Little Entrance started to silt up permanently. Some say this was due to dredging the channel for the PEI ferry. Whatever the case, the Little Entrance completely silted over and the flow of water in Caribou Harbour completely changed. It is now much shallower and the bottom changes due to tides, storms and ice. The beach at Caribou Provincial Park can be sandy one year and rocky the next, the bottom of Caribou Harbour shifts over each winter. Concrete blocks as big and heavy as an automobile used as barriers to erosion can be tossed like skittles by storm surges. The point is Caribou Harbour is an ever-shifting, highly sensitive environment that is rich in life. Lobster, herring, crab, oysters and other species are abundant. Fishing has shaped the history and the culture of this particular spot.

In Northern Pulp's proposal for a new effluent treatment facility I have found no mention of the impact of one tonne of solids to released daily into waters at the entrance to Caribou Harbour. In section 7.4.1 of Northern Pulp's registration document prepared by Dillon Consulting, there is no mention of a survey of Caribou Harbour or any studies of how water flows in an out of the harbour. The effect of the introduction of a massive infusion of water estimated to be over 62,000 cubic meters on a daily basis combined with a tonne of semi solid material has not been mentioned let alone analysed in terms of its impact on the harbour itself. Instead, Table E1.1-1 the claim is made that there will be No Significant Residual Environmental Effect Predicted. To anyone who witnesses the way Caribou Harbour subtly changes almost on a daily basis this seems to be an audacious claim. Caribou Harbour is a living entity and as such will be affected by the introduction of an effluent pipe.

I believe that Northern Pulp's Environmental Assessment regarding the issue of Caribou Harbour's Physical Environment, Water Quality and Sediment Quality is inadequate. I strongly recommend that your Ministry order an Environmental Assessment Report on this entire proposed project.

I also have very strong concerns about the location of the outlet for this pipe and its potential effect on the fisheries in area 26A. Figure 6.3-1 of the Executive Summary prepared by Dillon Consulting purports to represent the fishing done in the vicinity of Caribou Harbour, yet there is no indication of the herring fishery or the fact that the area around the north side of Pictou Island is a important herring spawning ground. Personally, I have seen herring swarming in Caribou Harbour to its most easterly extent up to the wharf operated by the Little Entrance Fishermen's Association. Again, I find the data presented in Northern Pulp's Environmental Assessment Registration Document raises more questions than answers. Given the significance of the fishery in Caribou Harbour, I feel that the Precautionary Principle that guides consideration of the environmental impact of an effluent pipe into the area of Caribou Harbour should preclude any potential threat to the rich aquatic life that spawns in these shallow waters. Caribou Harbour should be a protected estuarial zone and in no way should it be considered an appropriate location for an outlet for industrial effluent.

I would also like to ask the question: What significance is given to the cultural and historical aspect of Caribou Harbour? What consideration is there for the fact that generations of families living in the area consider Caribou Harbour a sanctuary for wildlife, a safe harbour for swimming, kayaking and sailing? It is the location of the Monroe's Island wildlife reserve, the Caribou Provincial Park and the Pictou Lodge, which has been in operation since 1927. The area has long been identified as a major area for outdoor recreation. Pictou County is defined by the generations of families who have earned their living from fishing lobster and other species in the immediate vicinity of Caribou Harbour. Within the communal rights of people living in the area to the peaceful enjoyment of nature and the established right of fishers to work in the area, the designation of Caribou Harbour as a location for an outlet of industrial waste seems to afford Northern Pulp a disproportionate right to the use of the waters of Caribou Harbour. This access threatens other citizens with the potential for an environmental disaster, the loss of livelihood and the loss of a unique habitat.

Fifty years ago, the proposal to put an effluent pipe from the Northern Pulp mill into the waters of Caribou Harbour where Maritime Packers was the largest employer in the county would certainly be met with disbelief and resistance. Is it surprising that disbelief and resistance is the response to such a proposal today? The reason remains the same: Caribou Harbour is too sensitive, too changeable, and too culturally important as a source of enjoyment and delight to be used as a sewer. With the fish stocks of Eastern Canada under threat and with the significance of Caribou Harbour to the tourist industry of the area this important marine environment should be afforded every protection from any source of pollution. I urge your Ministry not to approve Northern Pulp's proposal to install an effluent pipe into Caribou Harbour.

Sincerely,

Dear Minister,

I implore you to reject Northern Pulp's effluent treatment replacement proposal on the grounds that it will cause serious adverse effects to the environment.

My name is and I've lived in Pictou essentially my whole life excluding getting my education degree in NL. I hope to remain here.

I've never been a fan of the mill, especially when the wind is blowing a certain direction, but the economic benefits have always been impressed on me by others. Those no longer find merit with me. The environment has always lost against economic concerns. But I think the industry of the fishermen is equally as important as mill jobs. Tourism jobs as well. Also, I'd like to continue to enjoy my Caribou Island swims. That would end with the waste being dumped in the strait. Not to mention the environmental racism that has persisted for years here. Time's up for that.

Minister, it's 2019. The mill is well past it's intended lifespan. Let's innovate and re-train the mill workers. The treatment plan is dangerous and awful, this is your chance to be on the right side of history.

Sincerely.

Project: replacement_effluent_treatment_facility_project Comments: In regards to the effluent pipe being proposed. I was really looking forward to visiting and swimming in the Northumberland Straight for the first time, its quite unfortunate that this would be even considered. There is such a lack of empathy for people living in this area and the effects on their health. Ignoring the high rates of cancer hurts any opportunity for developing any other sort of economy, limiting Nova Scotias opportunities in the future and making the inevitable clean up more costly which the taxpayer will end up paying. To summarize I am against this proposal. Name: Email: @gmail.com Address:

Hon. Margaret Miller
Minister of Environment

Please find attached my submission to this environmental assessment.

Sincerely,

March 8, 2019

Hon. Margaret Miller
Minister of Environment
Nova Scotia Environment
PO Box 442
Halifax, NS B3J 2P8

Submitted via email ea@novascotia.ca

Dear Minister Miller,

I am writing to you with respect to the **Northern Pulp Replacement Effluent Treatment Facility Proposal.**

I live along the Northumberland Strait coast on Route 6, known popularly as the Sunrise Trail extending from Amherst to Pictou. Since emigrating from Scotland and landing in Pictou in the late 1700s, the Ferguson family has called the North Shore home.

I am very concerned about the future of the Northumberland Strait and the communities along its shores. I am requesting you reject the project proposal from Northern Pulp on the following grounds:

1. Adverse impact on commercial fisheries

Northern Pulp's proposal lacks important data on the risk to the fisheries making its claims that harm is "not likely" not credible.

I have family, friends and neighbours who depend economically on the commercial fisheries in the Northumberland Strait, notably lobsters and shellfish.

The Malagash Oyster has a flavour second to none. It is indigenous to the Malagash Harbour, once gathered by native Mi'kmaq and later by European settlers. This is a well established and reproducing oyster region. Bay Enterprises, operated by my neighbours the Purdy family, have been producing oysters since 1867. Today they use traditional and modern methods to sustainably farm oysters and quahogs, enjoying an international reputation.

Each oyster growing region in Nova Scotia possesses its own unique marine environment, including variations in salinity, temperature, tidal shifts, and mineral/chemical composition. This in turn, leads to the oysters of each area expressing different characteristics in shell shape, and, more importantly, in taste. Anything that alters or destroys this rare environment is putting this oyster at risk. Malagash Oysters are unique. To protect these delicious indigenous oysters we must protect their habitat from contamination.

Caribou Harbour, the proposed receiving site for the effluent pipe, is a critically important fishing and spawning ground for lobster, rock crab, herring, ground fish, and many other species. Damage to that habitat will have an adverse impact on communities throughout the Strait region.

2. Adverse impacts on human health

The Northern Pulp treatment system proposal includes a plan to burn the waste sludge. The waste sludge contains toxins which would be released through the stacks of the mill's power boiler. The proposal is to "dewater the sludge prior to mixing it with bark and other wood waste for combustion in the mill's power boiler."

This is the same power boiler that is currently and repeatedly failing stack emissions tests. Problems with air quality from mill emissions have been documented for years. Adding sludge containing toxins to the combustion mix increases the health risks from the mill's air emissions.

I don't have to go to Pictou to experience the air emissions from Northern Pulp. These emissions, depending on the winds, find their way to the trails I like to hike, the beaches I enjoy and the homes of friends I like to visit.

Airborne emissions of the mill are a significant health concern to me and I can find no evidence that Northern Pulp's proposal mitigates those pollutants.

3. Adverse impacts on the environment

The proposed treatment system runs the risk of harming the growing tourism industry along the North Shore which promotes the area's warm, clean water and world class sandy beaches.

Visitors are attracted to the North Shore by the many opportunities to enjoy the natural world, to consume high quality local food and beverage products, and experience small town life. Many of the thriving new businesses market these experiences.

Northern Pulp is already threatening the eco-tourism experience offered by these North Shore businesses. According to Deputy Minister of Environment, Frances Martin, your Department has taken 12 enforcement actions against Northern Pulp since 2012.[1]

With such a poor track record, how are we to have confidence in the claims from Northern Pulp that there will be no residual damage, by accident or design?

Moreover, monetary compensation is not meaningful mitigation for the destruction of natural ecosystems and their inhabitants.

In conclusion, with so much at risk, I urge you to honour the precautionary principle and reject this effluent treatment facility proposal.

Sincerely,

@gmail.com

New Glasgow Nova Scotia

I would like to first present some background before my submission. I am a proud of the late , from the 1930s to the 1950s ,was a Master Mechanic and efficiency genius in the employment of Maritime Steel and Foundries Limited , P&H heavy equipment of Milwaukie, Wisconsin, USA and the United States Department of War during the latter part of World War 2 . His innovations included the design of the mechanics of the Canso Strait Canal Locks, the design of Structural Lattice for the Canso Causeway Swing Bridge. , and I have generally inherited our quest to how things work and what are the most efficient practices in processes.

In the age of Internet research the abilities to find scholarly articles on subjects are indeed vast and instant on ones desktop . Choosing between truthful content or false leading information, to an ultimate political agenda, is not difficult. , was a highly respected journalist for and his teaching to us was to critically think and examine with an open mind. Everyone has Bias however there are sources that are honest and accurate. Tone and language used to communicate their given thesis or pronouncements is always the great indicator .

Before the Proposal for the Effluent Treatment facility for the Abercrombie Mill the Antigonish Town and County Library in their quest to have the ultimate in energy efficient computing.[1] A relatively unknown technology company named was what I found, recommended and sold to the Library. The task to find the solution was certainly not a simple one, considering the vast options in computing. I found ,via the Internet, the solution was a preferred computing option for the United Nations [2] Boeing and Nasa among many large and small private or public groups across the world.

With my Discovery , , I am happy to say in a recent visit to the Antigonish Town and County Library I found the system running as good as the day it was commissioned in 2011. This Install is the only one that I know in the world where all the computing stations of a public library work off PV Solar panels or batteries charged via PV solar panels. Thirty (30) sharing the computing capacity of Two CPU Servers saving 95 percent of the electrical power normally used in multiple seat computing setting.

My references for judgement of BAT or Best Available Technology have always been from well sourced information from Business and Governmental bodies. Procurement practices described in the forms of Press Releases,Trade Journals, Case Studies, White Papers and Scholarly articles are key to knowledge of technological and environmental subjects.

[1] "Case Study: Antigonish Town & County Library - Efficiency Nova Scotia." https://www.efficiencyns.ca/smart-energy-business-idea/case-study-antigonish-town-county-library/. Accessed 5 Mar. 2019.

[2] "NComputing and UN to Bring 500000 Workstations to ... - Litmos." 27 May. 2009, https://www.litmos.com/blog/industry-news/ncomputing-and-un-to-bring-500000-workstations-to-developing-countries. Accessed 5 Mar. 2019.

Public or Private sector procurement behavior generally occurs for salient well researched judgements for purchasing. Published documents with a price tag have much greater evidence value then that of Free opinion on the Internet.

On my extensive research of the proponents proposal. Veolia Anox Kaldnes BAS MBBR - Moving Bed Biofilm Reactor system

In my researched judgement the choice of the Veolia Anox Kaldnes BAS Moving Bed Biofilm Reactor system by the proponents ,Dillion Consultants and Northern Pulp, is indeed the Best Available Technology or BAT for treating Northern Bleached Softwood Kraft Pulp Effluent. The Anox Kaldnes BAS MBBR system has over 700 reference installations across public and private effluent treatment facilities. Over 700 multi-million dollar installations in the timespan of 30 years is an incredible amount of sales growth especially in the realm of Public Sector Procurement with municipal waste treatment facilities. If indeed Anox Kaldnes BAS MBBR did not work, as has been promoted, it would indeed not had grown to hundreds of installations approaching 1000 installations in a relative short time of 30 years. Simple Logic and a bit of knowledge of the nature of public and private procurement patterns tells me that sales of MBBR Systems are in the Multi Millions or even Billions of dollars since 1989.

As great footnotes I have seen online where Veolia Anox Kaldnes BAS is the sewage treatment system for Pictou Landing First Nations.[3] A First Nation that I can confirm via MERC tender documents as using the Veolia Anox Kaldnes BAS Moving Bed Biofilm Reactor system is the God's Lake First Nation in the province of Manitoba[4]
Also Notable is the Town of Ladysmith British Columbia installing a Veolia Anox Kaldnes BAS Moving Bed Biofilm Reactor system in 2018 with Federal infrastructure monies. The Following is part of the notated # 4 article on that system in an ecologically contained seawater environment in which Shell Fishing is an industry of the Area. "The harbour is of great importance to us and it's a shellfish harvesting area," said director of infrastructure services, Geoff Goodall. "It's always been one of our top priorities to ensure that whatever we are doing provided the best effluent quality possible."[5]

According to the Proponents EA documents the Pulp and Paper Industry has 40 MBBR systems installed to date with Swedish pulp and paper mills being 25 percent of the purchasers. In my research of other energy efficiency and ecological positive innovations, I have found Sweden to be one of the most progressive for developing or adopting world leading technologies in the Environment and Energy Efficiency arenas. Sweden's reputation is world renowned in environmentalism .

The Business and Governmental culture in Sweden seems to be forward thinking risk taking with great amounts of research before execution of new technologies. A prime example recent interest of mine, in which Sweden is a leading adopter, is that of R744 or Co2 Transcritical Refrigeration systems for Ice Recreational Facilities. Sweden and Quebec are the largest install territories for R744 in Ice Arenas in the World. Over the last four years I have personally compiled one of the world's most extensive R744 spreadsheets of refrigeration in Ice Facilities thanks in part to global R744 refrigeration experts in Stockholm, Sweden.[6] [7] The Quest that lead to the CO2 ice rink discovery was a Google Search for Energy efficiency in Ice Rinks in which I found the Natural Resources Canada Comparative Study of Ice Rink Refrigeration. [8]

The Original MBBR system was piloted in Norway in 1989 for a municipal effluent treatment system. The first pulp mill installation of the Anox Kaldnes MBBR was in Norway with a 1700 m3 system for Sande Paper in 1993. The Swedish Pulp and Paper Industry was soon to follow with a Pulp Mill Pilot project for Sweden was in 1994 for the Stora Papyrus Grycksbo Mill. Capacity of that system was 560 m3 and the results were detailed in the 49th Purdue University Industrial Waste Conference in 1994[9]. Purdue Study

Of the 40 MBBR Pulp Effluent treatment systems I have found 34 are located in the European Union and these MBBS Treatment systems seem to function to exacting standards of the European Union in Climatic Zones ranging from Spain to Scandinavia. A Recent discovery, I made of a new MBBR installation in Spain, found that the European Union had partially funded the system as a Best Available Technology option. Northern Pulp's proposal of 6000 m3 of MBBR to me is very sound in light of the European Union funding of MBBR in their member countries.[10] I also base my judgement on the fact that the Proponents proposed capacity of MBBR is indeed not the largest in existence in the Pulp Industry, Papelera Sniace in Spain with a reactor volume of 10690 m3 is. Papelera Sniace's MBBR was installed in 2010 and one would assume it has been highly successful considering two more MBBR s have been installed for the Spanish Pulp and Paper industry. My compiled list of MBBRs in pulp mill operations Note the Swedish Pulp industry has installed MBBR systems for close to twenty years MBBR Spreadsheet Created

Elemental Chlorine Free Vs Total Chlorine Free Bleaching

In Regards to the former owners of the Abercrombie Mill and the Switch to Elemental Chlorine Free Bleaching. Elemental Chlorine Free Bleaching with Chlorine Dioxide has turned out to be the winner of the ECF vs Total Chlorine Free debate . My research has found that since the year 2000 Total Chlorine Free Pulp Mills have been either A) gone out of Business like the Louisiana Pacific Mill in Samoa, California[11] B). TCF Mills been converted to make limited tonnage runs on a separate TCF lines parallel to a new ECF line like the Mercer Mills in Germany or C. Total abandonment of TCF to be replaced by ECF Bleaching like was the case with the Metsä Fibre Rauma mill TCF Mill in Finland. The Metsa Fibre Rauma Mill is a very notable TCF installation as it was the First New construction dedicated TCF mill in the world. Matsa Fibre Rauma was commissioned in 1996 and that Mill did not run the normal course of an investment return of decades ,in my limited observation, as the same mill was turned into a ECF mill in 2007. [12]
No new TCF Mills have been constructed in the Northern Hemisphere that I am aware of in the new millennium or a full 18 years and the reason seems to be clear. In a 2002 press release by the British Columbia Ministry of Water, Land and Air Protection ,the Honorable MP for Vancouver Quadra,Joyce Murray overturned a previous governments impending ZERO AOX law for Pulp mills in British Columbia. A scientific panel had found no appreciable differences in Effluent qualities from TCF VS EDF Pulp Mills[13] . There are three Pulp Mills in Europe that the proponents, Northern Pulp and Dillion Consultants, are patterning their effluent treatment plans from according to their submission. Here is an example of the European Market conditions as of 2017 from one of them. [14] Quote " **Although strong positions for TCF still remain in the German speaking region of Europe, some 95% of our European customers now use ECF pulps and this is basically us adapting to current market conditions. " Marcus Hellberg , Head of Business Development and Marketing , Sodra Cell**

Effluent Treatment systems for NSBK Pulp Northern Pulp is emulating with this Project

The Mercer International Stendal ECF / TCF Mill in Arneburg, Germany[15]
The Södra Cell Värö ECF/ TCF mill in Väröbacka, Sweden [16]
THe Södra cell Mörrum Paper and Dissolving Pulp Mill, Sweden

The addition of oxygen delignification at Abercrombie Point Mill is a basic element that all TCF / Hydrogen Peroxide mills require. Oxygen Delignification, from my investigations, has been a replacement Delignification process for TCF Bleaching which was once an Ozone Delignification process. The addition of Oxygen Delignification to the EA , in my opinion,is

a very forward thinking choice not only from a business potential standpoint but also from cost of production and ecological standpoints. On face value Oxygen Delignification added to the Bleaching process will indeed allow fewer chemicals to be used to produce quality Kraft Pulp via elemental chlorine free bleaching. If Global Market conditions have Total Chlorine Free Pulp become a profitable commodity then Northern Pulp may have than option. The Actions and Business course of Scandinavian Pulp Producers Metsa and Sodra however point to **Total Chlorine Free Pulp Bleaching as a Sunset industry** with decreasing Kraft Pulp Market share restricted 5 percent of the Global Market. [17]

Cooling Tower refrigeration - Natural Refrigerants VS HFC

In my recently acquired knowledge of Natural Refrigerants in Ice Rinks I found troubling information on HFC refrigerants recently. Trifluoroacetic Acid has presented some elevated Aquatic Toxicity in Beijing China according to studies[18]. HFC refrigerants are easy to avoid by choosing a Natural Refrigerants which the proponents have indeed done. I inquired to the Proponent the Refrigerant to be used in the Water Cooling System for the Effluent Discharge plant. Cooling will be done with the Natural Refrigerant R718 AKA H20 or Water.
HFC refrigerants also present the problem of high Greenhouse Gas Potentials of 1450 molecules of CO2 per molecule of HFC Refrigerants being typical[19]. NH4 Aka Ammonia has a GHG potential of Zero and CO2 has a GHG potential of ONE. [20]
I have fullest confidence in Northern Pulps Effluent Treatment proposal will lessen impacts on the the Environment and also human health effects by just these few forward thinking choices I have discovered via the EA . The bypassing of HFC refrigerants for the water cooling to a Natural Refrigerant is very forward thinking on Northern Pulp's Part.

Effluent Temperatures for Mixing zone offshore in Northumberland Strait
Concerns expressed by some stakeholders about effluent temperatures coming out of the Diffusers are probably very moot considering the pathway the pipe will take including 4 kms underwater in the last stage. Water Cooling of the Cooling Towers seems very plausible to have temperatures return to background levels within the 100 meter mixing zone. [21] MY personal discoveries and knowledge of Heat Recovery, in regards to Ice Rink systems, I have seen the transfer of recovery heat from an Ice complex is limited to 1000 metres away via Heavily Installed Pipe that is typically 12 inches in total diameter.

The proponents 36 inch Diameter **Un-insulated** HDPC pipe, running through 4 kilometers of seawater to the final diffuser outlets is very likely to lose a great deal of the original Effluent Plant Heat. Coupling the Aquatic Marine distance that the pipe will travel with the transfer

over approximately 800 metres across the Northern Pulp property to the Harvey Veniot Causeway, the elevated transfer above the Middle River spillway gates on the Harvey Veniot Causeway (with airborne exposure of the 36 inch pipe) being 30 metres in length, the 1.561 metres transit of the 36 inch Effluent pipe from the Pictou West River control gates to the Pictou Town end of the Harvey Veniot Causeway would probably have a good amount of thermal loss of the Treated Effluent inside the pipe. The Distance from the Pictou Town end of the Causeway to the Rotary is about 1300 metres . From the Pictou Rotary to Caribou Harbour is over 7300 metres in Length. My casual researched observations of heat loss from District Heating Systems, with highly insulated pipe that are not made of HDPC, leads me to believe that claims by the proponents are made with high levels of validity.

The proponents have exhibited a historical pattern of using BAT or Best in Technology that in at least one case have exceeded my expectations.

2014-2015 Precipitator Replacement - An example of the Proponents wise forward choices.

One only has to examine the results of the 2014/ 2015 replacement of the Abercrombie Mills Precipitator where prior to the 2014 precipitator failure the releases of PM 2.5 were 1,291 tonnes of PM 2.5 annually were recorded in 2014 via the Federal Department of Environment and Climate Change . The result according to the Canadian Federal Department of Environment and Climate is the installation of the new precipitator has resulted in a reduction of PM2.5 to 1.6 Tonnes in 2017. [22]
Northern Pulp 2017 report
A decline in PM 2.5, on an annual basis from 2014 of 1,291 tonnes in that year to 1.6 Tonnes of PM 2.5 admitted in all of 2017 is quite an improvement.
For the 2017 emissions of 0.125 percent of the 2014 total shows the proponent seems to have the best consulting and action plans to deal with environmental and public health challenges the operation of a NBSK Kraft Pulp Mill presents . Bellow, one page 7 is the recent history Table detailing the PM 2.5 emissions from the Abercrombie Mill .

[22] "Pollution and waste management - Canada.ca." 1 Oct. 2018, https://www.canada.ca/en/services/environment/pollution-waste-management.html. Accessed 6 Mar. 2019

PM2.5 (NA - M10)

Year	On-Site Releases				Disposal(1)		Off-Site Recycling	Units
	Air	Water	Land	Total	On-Site	Off-Site(2)		
2017	1.6	-	-	1.6	-	-	-	tonnes
2016	110	-	-	110	-	-	-	tonnes
2015	823	-	-	823	-	-	-	tonnes
2014	1,291	-	-	1,291	-	-	-	tonnes
2013	734	-	-	734	-	-	-	tonnes

In Conclusion

With simple research of the elements of Northern Pulps Effluent Treatment Facility ETF I feel highly confident that the proposal will not harm the Marine ecology of the Northumberland Strait in any Tangible way. The Six Rounds of Environmental Effects Monitoring for all Pulp and Paper mills in Canada ,since 1992, have shown the trend of aquatic ecologies improving in receiving bodies of water near Pulp and Paper Mills.
A similar Paper Excellence Mill in Howe Sound British Columbia is over 100 years old and has had continuous Upgrades in Process including the addition of Oxygen Delignification into their kraft pulp production, Changing from Chlorine Gas Bleaching to Chlorine Dioxide Bleaching AKA Elemental Chlorine Free Bleaching among many upgrades the entire industry has taken. Where once Howe Sound was closed for commercial and sports fishing, partially because of effluent contents of the Howe Sound and Woodfibre mills and mining operations, today it is no longer the case. Quoted from one of Canada's newspapers of Record The Globe and Mail " The first glimmer of hope came in 1988 when Howe Sound Pulp and Paper began a $1.3-billion renewal process at Port Mellon. The project would turn what was openly recognized as an environmental disaster into one of the most modern, cleanest pulp mills in the World " Mark Hume , Globe and Mail OCTOBER 21, 2013

“ Thou Paper Excellence is not the complete history of Howe Sound it is a much better history than the Mill prior to Paper Excellence.[23]

No human activity is without impacts however the Proponents proposed ETF will be a vast improvement from Boat Harbour that will continue the huge progress made at the Abercrombie Mill over the last couple of decades. With the introduction of ECF Bleaching in 1997 the environmental impacts have clearly improved , as represented by the results of multiple year EEM studies. I am highly confident science and the history of Northern Pulps environmental investments will continue with the approval of this proposal. I first personally took notice when the Mill was converted from the use of Bunker C Oil to Natural Gas for proposes inside the plant.

Thank You Very Much

Subject: Proposed Project Comments
Date: March 8, 2019 10:09:04 PM

Project: replacement_effluent_treatment_facility_project Comments: I am writing in connection with the Environmental Assessment Registration Document hereafter â?oEAâ? submitted by Northern Pulp of the Replacement Effluent Treatment Facility. I have read carefully the document and its supporting documentation and am gravely concerned about many of the potential devastating impacts the proposal may have on the environment and, in particular, the Northumberland Strait ecosystem. As an initial point, I feel that the public consultation period of 30 days for a project of such complexity is woefully inadequate. The EA is thousands of pages in length, with multiple supporting documents, and covers a broad range of topics. For meaningful engagement to take place, considerable additional time should have been allowed. By way of background, I am a geoscientist, with a PhD in Geology from the University of New Brunswick, working primarily in the field of marine geoscience. My family have a cottage on Caribou Island and I have enjoyed many days of recreational boating and fishing in Caribou Harbour. As such, I am very familiar with the coastline, seabed and tidal conditions of the area of the proposed effluent outfall pipe. While I have reservations over many aspects of the project for example, the transport of the effluent through a pipeline that crosses above the water source for the Town of Pictou, I will restrict my comments here to those aspects of the EA that I have some familiarity with and specific scientific based concerns about. Specifically, these will focus on the proposal to pipe effluent to a discharge point close to Caribou Wharf. The environmental effects are dealt with in Chapter 8 of the EA with the harbour physical environment described in Section 8.11. The descriptions provided of the area around Caribou Harbour are very general relying on regional scale syntheses and existing reports that focus on existing data which in many cases are quite old see for metal concentrations in sediments on Table 8.11-1 from 1990. Any monitoring of the marine environment and assessment of the impacts particularly potential ongoing impacts should have a robust baseline dataset. The EA clearly does not have purposely acquired primary data and relies on inapplicable, insufficient or inappropriate datasets and studies. Physical Hazards Sedimentation â?" The Northumberland Strait coast of Nova Scotia is a dynamic marine coastal environment with longshore drift transporting and depositing sediments typically from West to East. This is particularly evident at the mouth of Caribou Harbour where a large sand bank occupies much of the western side of the mouth. This is clearly visible through satellite imagery for the area and is the cause for the requirement to dredge the navigation channel for the PEI ferry that departs from Caribou Wharf. The development of a significant sand bank on the lee side of Caribou Point is entirely expected where longshore drift is a dominant process and environments such as this are highly mobile sedimentary environments. This represents a burial danger for the diffusers which would impact the effectiveness of the assumed dilution of effluent in the water column. If the diffusers cease to work as designed, concentrations of effluent could exceed the CCME guidelines for Marine Aquati c Life causing fish kills. Furthermore, the process of monitoring the condition of the diffusers is greatly diminished if it becomes buried. The prospect of having to excavate sediments to ensure the diffusers function as designed risks damage and further degradation of the marine environment. This was not addressed in the EA. On a related point, the proposed effluent pipeline routing is along the western edge of the dredged navigation channel. This channel is dredged on a relatively frequent basis. The dredging operation typically takes the form of a large excavator on a barge â?" a rather imprecise procedure. The possibility of damage to the pipeline by dredging operations would seem quite high. Ice Keel - The Northumberland Strait is well known for

significant ice development and accumulation in the winter season. In a comprehensive study of ice keel data from the Northumberland Strait, Obert and Brown 2011 report average ice keel depths of 2.94 m with a maximum of 8.49 from the PEI bridge. The EA cites a NS Museum of Natural History report 1996 that states that â?o[c]oastal lagoons in the Northumberland Strait area are protected from ice scourâ?. The outfall for the effluent pipeline is located beyond the mouth of Caribou Harbour and therefore this statement would not seem to apply. Even the ice keels in the Caribou Harbour mouth region were significantly smaller than those noted above, it seems plausible that damage to the pipe could happen by ice keel scouring in the winter months. Physical Oceanography The EA is deficient in describing the physical oceanography of the local environment. Assessments of salinity, temperature and tidal currents are based on measurements and models for the entire Northumberland Strait and southern Gulf of St Lawrence. For a project whose potential effects may have such a profound influence on the marine environment of such an enclosed bay and whose effects, in large part, are determined by physical oceanographic processes, there is a striking lack of detail and analysis. The understanding of tidal currents for the area is entirely insufficient. The EA cites modelling of tidal currents from DFO in Figure 8.11-3 which covers the entire Northumberland Strait without providing any additional context or information. The semi-enclosed nature of Caribou Harbour presents a localised complexity with understanding the tidal pattern in the region. This was not addressed in the EA. The degree to which tidal mixing occurs is not addressed in any detail. The Northumberland Strait has some of the lowest tidal mixing in the Gulf of St. Lawrence Lu et al., 2001. Coupled with the localised coastal geography, it is quite possible that the current/flow regime in the area of the proposed outfall is not conducive towards effectively diluting the effluent discharge. This brings me to the numerical modelling supplied in the EA Appendix E that purports to show that the effluent becomes rapidly diluted within the water column. The stated model parameters and results are quite simply not scientifically valid and cannot, in my view, be used to support any decision making by the regulator. If decisions are to be science-based then it is important that the science being presented is credible and broadly acceptable to the scientific community. Below is a non-exhaustive list of major problems with the proposed modelling results: â?¢ The effluent concentrations are not described or defined. Different components e.g. dissolved solids, metals, organic material etc. will behave in a different manner in the water column and this was not accounted for. â?¢ The modelling results indicate that there are few isolated traces of relatively high diluted effluent after a period of 30 days see pg 350 of the EA and figures 2.5 to 2.13 of Appendix E, but effluent discharge will be continuous. If a continuous flow is assumed, it is physically impossible for there to be an isolated concentration of the effluent away from the discharge location. â?¢ The modelled ambient flow directions shown in Figure 3.1 of Appendix E show a dominant northwest direction flow. This is counter to local knowledge and the stated understanding cited in the EA itself: â?oThe current in the Northumberland Strait generally ï¬,ows in a southeasterly direction between New Brunswick and Prince Edward Island PEI Nova Scotia Museum of Natural History 1996.â? see pg 338 of the EA. â?¢ The shape of the dispersal plume from the diffuser as shown in figures 3.4 and 3.5 of Appendix E is utterly unrealistic. This suggests a numerical weakness in the model that undermines any confidence in its output. The tidal modelling and contaminant plume dispersal model is scientifically not credible and should at a minimum be subjected to rigorous peer review. The Caribou-Munroe Island Provincial Park is located less than 2 km from the proposed outfall location and the proposed effluent pipe will be within 400 m of the Provincial Park. The website for this Park currently states â?oCaribou-Munroes Island Provincial Park invites you to experience northern Nova Scotiaâ?Ts unspoiled natural beauty. Conveniently located along the Sunrise Trail just a few kilometres from the Caribou-Wood Islands Ferry Terminal, the park features secluded,well-wooded sites that offer privacy in a natural

setting.â? https://parks.novascotia.ca/content/caribou-munroes-island-hiking-trails Is the current government planning on amending this description to include that the recreational activities are located immediately adjacent to an effluent outfall? Currently reviews for this park on Trip Advisor state that the beach is lovely, the wilderness is beautiful, however, it is stinky due to the Pulp Mill https://www.tripadvisor.ca/ShowUserReviews-g154977-d2306605-r140010740-Caribou_Munroes_Island_Provincial_Park-Pictou_Nova_Scotia.html. Furthermore, it seems that without a permit from the Minister of Lands and Forestry the proposed effluent outfall should not be allowed. The effluent is, by definition, a hazardous or industrial waste. Section 24 of the Provincial Parks Act R.S., c. 367, s. 1 states: â?oNo person shall transport garbage, refuse or domestic, hazardous or industrial waste through, over or in any provincial park or deposit such material in or on a provincial park, except as may be authorized by permit issued by the Minister.â? The proposed location of the effluent outfall seems at odds with the purpose defined in Section 2 of the Provincial Parks Act. A source of contamination is not compatible with â?oproviding resident travellers and out-of-Province visitors with opportunities to discover, experience and enjoy Nova Scotias distinctive outdoor recreational and heritage resourcesâ? Section 2.1.d of the Provincial Parks Act. The Caribou-Monroes Island Provincial Park was not included as a Valued Component VC in the EA document. Given the proximity of the park to the outfall location, it should be included as a VC and have a full environmental effects assessment. Caribou Wharf is the home port of many fishers who make a living on the waters of the Northumberland Strait. Their knowledge and years of experience fishing these waters is unrivalled. Their near unanimous opposition to the proposed pipeline is telling and, in my view, should be heeded. To conclude, there is simply too much at stake to grant the approval of the project based on the EA submitted by Northern Pulp. In my view, the EA does not contain sufficient data or analysis of the marine environment in and around the region of the effluent outfall pipe. The EA has not taken into account the physical dangers to the pipe infrastructure and the potential behaviour and effect the effluent outfall will have on the marine environment. Subject: In support of Northern Pulp"s EA application
Date: March 8, 2019 10:14:18 PM

I am writing in support of the Environmental Assessment application submitted by Northern Pulp for its new treatment facility.

A lot has been said about Northern Pulp and its impact on the local community. I stand in agreement with many, including Unifor, that Boat Harbour must close and be cleaned up to respect Pictou Landing First Nations people and their land. I also know there are many positives about having 300 good-paying jobs in Pictou, supporting thousands more across Nova Scotia, particularly in rural communities.

The Nova Scotia Environment Act is an essential piece of legislation designed to protect our shared environment and guide our economic development. The Act rightly spells out its purpose through a set of principles for sustainable development that should guide its application, including:

------> The linkage between economic and environmental issues, recognizing that long-term economic prosperity depends upon sound environmental management and that effective environmental protection depends on a strong economy.

In this situation, science should determine the best path forward. Nova Scotia, along with the rest of Canada, has among the highest global standards for environmental stewardship in the forestry sector.

The job of government and every person we elect to represent us in government is to find the best way forward when there are many competing and sometimes opposing interests. Communities across Canada manage to find a fair balance where good mill jobs coexist with a prosperous fishing industry and thriving communities.

We can and must find this balance for Pictou. There is a lot at stake: jobs, the environment, and respect for First Nations. We can and must find a solution that supports all three.

Thank you.

Forestry and Fishing are very important sectors and have and can continue to co-exsist side by side and mills plan will put them atop of pact in regards to the environment and meeting regulatory standards. Mill should be given the time to do put in their treatment plant as all Nova Scotians will benifit

Subject: Please reject NP's replacement effluent treatment facility proposal
Date: March 8, 2019 10:59:37 PM

Hello,

I am writing to ask you to please reject Northern Pulp's effluent treatment replacement proposal on the grounds that it will cause adverse effects that significantly outweigh any potential benefits of allowing it.

If the proposal is approved, it will allow an aging facility to limp on for a few more years while posing serious potential risks to the Pictou area. If the proposal is rejected, it is likely that the mill will close. , director of communications for Paper Excellence has been quoted as saying "No pipe equals no mill" [1]. I believe this is the ideal outcome. Here are a couple reasons why:

1. The Pictou Landing First Nation people don't want it [2] - and for good reason. The existing effluent pipes have leaked several times in the past [3]. It's time to listen to them. The shameful history of environmental racism in Boat Harbour makes our whole province look bad and moving the effluent dump of an old pulp mill across land and out into beautiful waters full of sea life doesn't make it any better. It's time to get rid of the mill and put an end to that whole miserable saga.

2. Tourism. The pulp mill is a huge blight on an otherwise picturesque tourism destination in our province. Why approve an effluent pipe that is at best an environmentally risky means of allowing an outdated operation to limp on a few years longer? The loss of 300 jobs [4] is not nothing, but those people all have the potential to do other things. Tourism is one industry poised to improve if the mill closes. Real estate is another. The waterfront properties in Pictou Harbour would be worth more and the town of Pictou waterfront would be so much more enjoyable if it wasn't for the eye(and nose)sore that is the pulp mill. Pollution from the mill stinks. It stinks up the entire area surrounding Pictou Harbour. I visit my family in Pictou regularly and can attest to how bad it smells. Other people without family in town don't like to visit because it's so often smelly there. Even if the airborne pollution from the Mill had no negative impact beyond stinking and looking bad, the stink especially harms tourism (and quality of life in the Pictou area). The same would be true of the effluent that would be coming out of the pipe into the strait if the proposal is approved. There are several beaches within 2 km of the proposed pipe outlet [5], including Caribou-Munroes Island Provincial Park [6] and the beaches surrounding the Caribou Island Lighthouse [7]. Those beaches are great for swimming and watching the many curious seals and diving seabirds from, but people will think twice about swimming so close to effluent and worry what poor sea creatures might wash up and scare their kids at the beach.

For the reasons described above as well as the many environmental concerns I'm sure others have voiced to you already, I implore you to please reject the proposal and play a role in putting the pulp mill to rest.

Good evening ,

In addition to the technical review submitted earlier today by Shared Value Solutions on behalf of the Gulf Nova Scotia Fleet Planning Board, and their Fishermen's Working Group for the Northern Pulp Environmental Assessment, I am attaching and additional document including three appendices as part of our review of the NPEA.

Please note, we will will be forwarding you an addendum to this submission tomorrow.

Thank you in advance,

Linda Townsend

EXECUTIVE SUMMARY

CrustiPath was engaged by the Harvester Working Group to review the January 2109 Environmental Assessment (EA) on the Northern Pulp Nova Scotia replacement effluent facility. The focus was to be on the health of the fish, crustaceans and bivalves; specific to local commercially important species including an understanding of how contaminants in the effluent may negatively affect the reproduction and growth rate. After a preliminary review of available information and given the very short timeline available, it was decided to focus the review on the changes known or potentially possible to happen to crustaceans, particularly American lobsters

Although improvements in treatment of BKME have decreased acute toxicity (mortality) to fish, effluent from pulp and paper mills continues to release bioactive substances that affect fish metabolism and reproductive performance. The identity of the responsible compound(s) remains undetermined. The roles of hormones e.g., estrogens, androgens, anti-estrogens, anti-androgens, neuroactive substances and altered nutritional effects are possibilities. There are reports of moult inhibition in crustaceans exposed to estrogenic, androgenic, anti-estrogens and anti-androgens. Five studies on American lobster (*Homarus americanus*) exposed to BKME from Abercrombie Point between 1968 and 1973 suggested: larvae were relatively resistant to BKME and adult lobster more so; no significant change in larval numbers after opening of the mill; and, that lobster movement and feeding behaviour were unchanged at low levels of BKME. The latter could also be interpreted as an inability to detect and avoid potentially deleterious BKME. These studies were limited in scope, used BKME different from that anticipated to be produced by the NPNS, and did not include sublethal toxicity or generational testing. These limitations were noted in Appendix R of the EA, but not mentioned in Section 8.12.3.3. There are few data on the sublethal effects of exposure of crustaceans to the pulp mill effluents created today e.g., elemental or total chlorine free, secondary biological treatment, particularly in marine environments.

Section 9 of the EA (Human Health Evaluation) used model studies to identify cadmium, mercury, selenium, (and polychlorinated dibenzo-p-dioxins and dibenzofurans (PCDD/F)) as chemicals of potential concern (COPC) that might accumulate in tissue of fish exposed to effluent. While the intent was to examine the fish tissue from a food safety perspective, it could also be concluded that these chemicals also represent a health risk to species in the receiving waters. With respect to crustaceans, cadmium has been shown to negatively effect moulting and growth, reproduction, and cause variation in hemolymph glucose (sugar) levels, possibly via an 'endocrine disruption' effect. Anticipated levels of these COPCs in the effluent are not provided in the EA, precluding assessment of possibility toxicity to crustaceans.

The current Environmental Effects Monitoring (EEM) program uses the caged blue mussels (*Mytilus edulis*) as a representative invertebrate for testing purposes. Bivalves are different from crustaceans in many ways. It would be desirable to know if bivalves and crustaceans respond similarly to BKME for EEM purposes.

Development of a new reef structure creating habitat for lobsters and other fish as a result of the pipe infrastructure is mentioned. Whether or not this would encourage fish to stay near the outflow in an area of maximal effluent and whether this could have a negative, neutral or positive effect on fish health is not discussed.

Given the limited, and often dated, information available regarding the potential for adverse effects on the health, in particular growth (moulting) and reproduction, of marine species of commercial interest such as the American lobster and rock crab, upon exposure to the mill effluent to be produced by the proposed facility at NPSNS, further studies (acute, sublethal, and generational) are recommended.

SCOPE OF REVIEW

The overall pertinent sections of the environmental assessment (EA) were reviewed: Section 8.12 Marine and Fish Habitat, Section 9 Human Health Evaluation, Appendix G Proposed EEM Program, Appendix H Proposed Follow Up and Monitoring Program, Appendix R Scientific Literature BKME Effects on Lobster, and the 2016 EEM report and summary documents. Literature searches on: the historical effects of BKME on finfish, bivalves and crustaceans; known or proposed mechanisms of action of BKME; effects of BKME on finfish, bivalves and crustacean since the introduction of new effluent treatment measures; and known or suspected effects on crustaceans of the chemicals of potential concern (COPC) identified in Section 9 of the EA. There is heavy reliance on the review paper by Hewitt at al in 2006 regarding the chemistry and effects of BKME. The conclusions and recommendations are based primarily on the information provided in the EA and how it relates to published information on crustaceans rather than a global review of potential health effects to marine species exposed to BKME.

CONCEPTS OF HEALTH

Animal, or human, health can be loosely defined as an absence from disease. Disease can be defined as the impairment of normal function or structure of a living organism. A more specific definition of health is provided by the World Health Organization (WHO) and states the following "Health is a state of complete physical, mental and social well-being and not merely the absence of disease or infirmity (Grad, 2002). The presence of disease be assessed by looking at changes in physiological systems e.g., respiratory, reproductive, immune, integument (skin, shell, carapace), muscular, skeletal and nervous systems, and behaviour. Testing methods can include: physical examination; changes in weight; collection of blood (or hemolymph) samples to test e.g., immune function, organ function or toxin accumulation; pathology exams at the gross or microscopic (histology) level; gene expression; and, more recently metabolomics.

Pulp Mill Effluent Effects on Finfish Health

The review paper by Hewitt et al. (Hewitt, Parrott, & McMaster, 2006), summarises the path of research of two identified responses in finfish exposed to pulp mill effluent 1) induction of detoxification enzymes (suggesting exposure to a toxin) in fish tissues, and 2) reproductive effects e.g., "smaller gonad (ovary) and egg size, increased age to maturation, decreased levels of reproductive steroid hormones, and altered expression of secondary sex characteristics". The earlier focus on absorbable organic halides (AOX) switched to bioactive substances released from the wood during pulp digestion (in kraft mills, present in black liquor and chemical recovery condensates). Of note is the study of the **AhR** (aryl hydrocarbon receptor), cytochrome **cyt p450,** P-4501A1, and **EROD** (ethoxyresorufin O-deethylase) molecules which are involved in the detoxification process.

The authors note that despite the improved quality of effluent with decreases in compounds producing acute toxicity (mortality), organochlorine discharges and AOX levels, effects persist *"…, effluents from pulp and paper mills continue to release into Canadian aquatic receiving environments bioactive substances that affect fish metabolism and reproductive performance*" (Hewitt et al., 2006). The authors also note in their conclusions that "*The bioactive substances in pulping processes appear to be derived from original pulp digestion and/or from residual lignin removal during bleaching. The identities of the responsible compounds have remained elusive, thereby impairing any evaluation of the effectiveness of secondary treatment and other process changes in the industry*".

A review in 2010 (van den Heuvel, 2010) indicated that reproductive impairment noted in fish exposed to pulp and paper effluent, although decreasing, continues and the causative agent(s) remains to be definitively identified. Exposure to hormones (estrogenic, anti-estrogen, and androgens) derived from the wood itself, neuroendocrine compounds that interfere with hormone balance, or nutritional effects are possible mechanisms under consideration. The metabolic disruption response (decreased gonad size associated with increased liver size and greater body condition) "*remains a prevalent pattern in data generated as part of Canada's federally mandated Environmental Effects Monitoring Program*" (van den Heuvel, 2010).

A long term review of effluent at a mill in New Zealand concluded that subtle effects on fish reproductive physiology, while substantially decreased, continue to be observed even with extensive efforts to improve the quality of the effluent (van den Heuvel, Slade, & Landman, 2010). The example described was that of swim-up fry being substantially shorter and lighter than fry from the reference site. This was attributed to a chronic, eight- month, exposure of the maternal fish to the test effluent, suggesting a next-generation effect.

Interestingly, Davis et al. (Davis et al., 2013), used metabolomics (the study of a set of metabolites within a cell, tissue, or organism) to demonstrate short term response of fathead minnows to short term changes in effluent levels in Lake Superior during a temporary shut down of a paper and pulp mill in the region. The effect was most pronounced in male fish… "*Thus, we demonstrate the potential utility of field-based metabolomics for performing biologically based exposure monitoring and evaluating remediation efforts occurring throughout the Great Lakes and other ecosystems*". This represents another potential way to assess fish health.

Pulp Mill Effluent Effects on Crustacean Health

The effects of BKME on crustacean physiology are not as well studied as in fish. Crustaceans have a complex endocrine (hormone) system that is responsible for regulating reproduction, growth and moulting, and metabolism as in vertebrate species. The effects of pollutants (pesticides, herbicides, effluents, heavy metals) on the physiology of these animals are not as well documented as in fish, birds and mammals. Review papers by Fingerman (Fingerman, Jackson, & Nagabhushanam, 1998) and Rodríguez (Rodríguez, Medesani, & Fingerman, 2007) concisely summarise some of these endocrine (hormone) disruptive effects and the known or suspected mechanisms in crustaceans.

Disturbance or disruption of the normal processes of reproduction and moulting were the most common effects studied. While many of these were ascribed to pesticides, xenoestrogens (synthetic or naturally occurring compounds that mimic estrogen), testosterone (an androgen), juvenoids (synthetic compounds designed to mimic the structure or effect of insect juvenile hormone; often used as insecticides) the impacts of the metals cadmium, and to a lesser extent, copper, mercury and zinc are also described (Rodríguez et al., 2007). In their concluding remarks, the authors stated "*crustacean molting can be inhibited by any one of several organic compounds (including androgenic, estrogenic, as well as antiandrogens and antiestrogens) as well by some heavy metals."* The need for further study to determine mechanisms, with an emphasis for multigenerational studies to assess long-term processes such as reproduction and growth was emphasised (Rodríguez et al., 2007).

Cadmium has been associated with moult inhibition in the crab, *Chasmagnathus granulatus* and *Daphnia magna,* and inhibition of ovarian growth in fiddler crabs (*U. pugalotor*) exposed to cadmium for two weeks (Rodríguez et al., 2007). Cadmium is suspected to inhibit moulting by inhibiting the secretion of the moulting hormone ecdysone (Rodríguez et al., 2007). Lethal concentrations (LC-50 at 96 hours) of cadmium, copper, and mercury for stage I *Homarus americanus* larvae were determined to be 78 µg/L, 48 µg/L, and 20 µg/L, respectively (Johnson & Gentile, 1979). Heavy metals can inhibit food intake by small crustaceans (Rodríguez et al., 2007). Changes (transient increases (hyperglycemia) in acute exposures, decreases in chronic exposures) in hemolymph (blood) glucose levels in response to metal exposure have been documented in crayfish and in the shrimp *Palaemon elegans* exposed to mercury, cadmium, and copper crabs (Rodríguez et al., 2007). Chronic (two week) exposure to cadmium in the crab, *Chasmagnathus granulatus* appeared to interfere with crustacean hyperglycemic hormone (CHH) – the crustacean 'stress hormone' and lowered hemolymph glucose levels.

Information on the specific effect of BKME on American lobsters is extremely scarce with all five papers found during a literature search being written before 1973 (McLeese, 1970, 1973; Scarratt, 1969; Sprague & McLeese, 1968a; Sprague JB, 1968b).

Comparisons of surface plankton tows conducted in 1966, before opening of the pulp mill at Abercrombie Point, and in 1968 after the mill had been in operation determined that the variation in total catch of 746 larvae in 1968 from 1814 larvae in 1966 was within the range of normal catch fluctuations in the Strait (Scarratt, 1969). The study concluded that "*the mill effluent was not having any immediate, direct effect on the abundance and distribution of lobster larvae in the Pictou area*." No

measurements (weight, length), gross or microscopic observations for abnormalities or adverse effects are reported.

One day old American lobster larvae and adult lobsters were exposed to a range of diluted BKME and acute toxicity evaluated (Sprague JB, 1968a). The BKME represented a mixture of material from the bleachery 'chlorination effluent', (40%), bleachery 'caustic extraction effluent' (30%) and effluent from the kraft screen room sewer (30%) and neutralised to pH 7. The authors concluded that larvae were reasonably resistant to BKME concentrations below 10% and that adults were "*even more resistant*". When comparing the responses of salmon parr (*Salmo salar* L.) and *Homarus americanus* larvae to biologically oxidised BKME, lobster larvae were described as more sensitive than parr at the one week time point, suggesting different responses by different animals to the same conditions (Sprague & McLeese, 1968b). There was no histologic examination of tissues to assess for injury, long term, sublethal, or generational effects evaluated for survivors in either study.

Adult American lobsters to exposed to 10% - 20% BKME (spillway material) in a test tank passed through the BKME-seawater boundary 98 out of 103 approaches (McLeese, 1970). Of the five initial reversals, lobsters passed through the boundary on subsequent approaches. The conclusion was that 10% - 20% BKME did not affect movement of adult lobster. A later study examined if BKME would alter the feeding response of American lobster in the presence of BKME (McLeese, 1973). It was concluded that "*exposure to low concentrations of BKME for short periods does not reduce the response of lobsters to freeze dried cod solution or, if so, to a minor extent only*". The investigator also indicated "*the possibility that long term exposure might affect the response, or that other behavior stimulated by chemoreceptors may be affected, was not tested".* An additional interpretation of these results is that failure to avoid the effluent might represent a risk to the health of the lobster if there is a component in the effluent that could generate an adverse effect in the lobster.

While these studies did investigate the effect of BKME on American lobster specifically, it is important to note that the effluent composition has changed over the past 50 years (Hewitt et al., 2006; van den Heuvel, 2010) and probably does not reflect what would be entering the receiving waters in the current proposal. The studies were relatively limited in scope and depth – essentially looking at acute toxicity data, a behaviour response, and one abundance and distribution study. These represent very limited investigations by current standards with a notable lack of sublethal, chronic exposures or examination of generation effects, assessment of growth or reproduction indices, etc.. The relevancy of the findings in these studies to the composition of the effluent, which is not clearly defined within the EA, from the proposed NPNS effluent treatment facility is uncertain.

A study of the decapod crustacean, *Pacifastacus leniusculus,* a freshwater crayfish, demonstrated induction of cytochrome p450 in response to dioxin (TCCD) exposure (injected) (Ashley, Simpson, Holdich, & Bell, 1996). The response may have involved the AhR system as noted in vertebrates. This is an interesting finding as it could mean that crustaceans have the potential to respond to BKME in a manner similar to fish. Expression of genes for cytochrome p450-form has been studied in American lobster (Tarrant, Franks, & Verslycke, 2012). This suggests that physiologic responses of American lobster could be studied at the gene expression level as in finfish.

More recently, Chamorro et al. (Chamorro et al., 2016) investigated the sublethal effects of chlorine-free kraft mill effluents using the small freshwater crustacean, *Daphnia magna* as the model species. This is a tiny, freshwater, planktonic, water flea used in studies for ecologic monitoring purposes. The study was conducted to address the concern of biologically active compounds that might remain in wastewater despite the use of chlorine-free bleaching and biological treatment of wastewater. A chronic feeding test and two standardised tests - an acute lethality test, OECD 202 (Organisation for Economic Co-operation and Development., 2004) and a chronic assay testing reproduction, OECD 211 (Organisation for Economic Co-operation and Development., 2012) were used. The latter "uses reproduction as a basic biological endpoint, but the test design allows for the measurement of other relevant variables like mortality and growth". The investigators reported mixed results with stimulatory effects on some parameters at low concentrations of effluent while reproductive effort was reduced at higher concentrations of effluent. The potential for this to be a hormetic effect, where a biphasic dose response to an environmental agent characterized by a low dose stimulation or beneficial effect and a high dose inhibitory or toxic effect was considered (Mattson, 2008).

The reproductive assay and the chronic feeding test are directly and indirectly looking at animal health and examining for sublethal effects. Further investigation as to the applicability of these tests to a marine environment and/or extrapolation of any results to larger decapods and species of commercial interest requires further investigation and is beyond the scope of the current report.

Taken together, these studies suggest the potential for impact on crustacean health by several organic compounds (androgenic, estrogenic, antiestrogenic, antiandrogenic) which have suspected roles in impaired reproductive potential in finfish exposed to BKME. Metals such as cadmium that could be present in BKME are also recognised to impact growth and reproduction in crustaceans.

COMMENTS ON SELECTED SECTIONS OF THE ENVIRONMENTAL ASSESSMENT SUBMITTED BY NPNS

Section 8.12.3.3 Characterization of Residual Effects

The report on scientific literature of BKME effects on lobster (Appendix R) summarises literature on responses of American lobster, *Homarus americanus* to BKME and related salinity, temperature and dissolved oxygen changes. The limitations and the need for further study, including sublethal testing using current BKME was indicated in the executive summary and in the report's concluding remarks as follows: "*Studies to more accurately assess the potential for impact to adult lobsters including lethality, behavior, and sublethal impacts are recommended to be carried out with current treated BKME. Completing studies of lobster larvae with today's treated BKME would allow for confirmation and better understanding of potential lethal and sublethal effects."*

These recommendations are valid and appropriate; however, do not appear in Section 8.12.3.3 (Marine and Fish Habitat. Impact Evaluation/Effects Assessment. Characterisation of Residual Effects) where much of Appendix R is referenced.

The concept of a reef effect at the site of the pipe is mentioned as a beneficial aspect of the change "from a soft-bottomed benthic community to hard-bottom community". It was also noted that "*Marine plants, which are important components of habitat for lobster and other commercially important species, will also colonize the hard substrate of in-water structures*." While it may provide new habitat, the potential to encourage animals to feed and remain close to the outflow site might have the unintended consequence of increasing the exposure of animals to the effluent. The studies by McLeese suggested that adult American lobsters would detect and consume feed in the presence of BKME of the day (McLeese, 1970, 1973). The effects on marine animal health of this behaviour are unknown and would be an area for further evaluation.

Environmental Effects Monitor (EEM) for Monitoring Stage (Appendix G)

Appendix G provides an outline of the components of an EEM program should the NPNS EA submission be approved. It states that modifications from the current EEM will be required to address the change in treatment plant and discharge structure. The current EEM uses caged bivalves (*Mytilus edulis*), blue mussels, as *"Caged bivalves provide a reasonable alternative to finfish to assess the effects of pulp and paper effluent on fish* (Environment Canada, 2010) when marine discharges are used .

The assays to be conducted on caged mussels include*: "Various morphological measurements will be made on individual mussels (shell length, shell width, shell height, whole animal weight wet (WAWW), soft tissue fresh weight, and, gonad somatic index (GSI)) in order to generate measures of key potential effect endpoints, such as reproductive effort, growth, energy storage and survival."*

As the crustaceans, American lobster and rock crab, represent two of the commercial resources identified in the EA, it would be reassuring to see evidence that the caged bivalve system is also an approved alternative for crustacean species. This information could not be found in the EA.

Proposed Follow Up and Monitoring Program (Appendix H)

"*Follow up and Monitoring will include: sublethal toxicity testing of treated effluent; phytoplankton and zooplankton community assessments; benthic invertebrate community sampling; water quality sampling; fish community and fisheries resource characterization; and fish and shellfish tissue chemistry investigations*". More detailed monitoring is proposed in the event that "*monitoring results indicate that either end-of-pipe effluent quality data or receiving environment data deviate from those predicted in the EA the potential consequences (if any) of such deviations would be investigated. In this instance, additional or modified performance monitoring components could be proposed and/or implemented, as appropriate"* or *"Alternatively, where EA-related predictions are confirmed reduced monitoring effort may be indicated".*

Tissue chemistry monitoring would include collecting tissues from potential species of interest including lobster, rock crab, scallop, blue mussel, softshell clam, oyster, and locally relevant finfish (e.g., Eel, Smelt, Gaspereau, Striped Bass, Mackerel, Atlantic Herring). *"Tissue specimens will be collected from the exposure area (i.e., the area potentially influenced by mill effluent) and up to two reference areas that are beyond the potential zone of influence of the effluent. Overall, it is envisioned that 5 to 8 replicate samples of 3 to 4 species from 2 to 3 sampling areas will be submitted for analysis of the following parameters: total phenols; total metals contents; low level mercury; and, resin and fatty acids.*

Tissue chemistry testing will generate data on the levels of these chemicals in fish tissues (presumably for use in food safety assessments) but is only an indirect assessment on the health of the fish and shellfish themselves. If the sublethal testing is limited to bivalves, it is unknown is this would adequately reflect effects on crustacean health.

Section 9.0 Human Health Evaluation (as pertains to marine health)

As part of the review of human health risks, a report by Toxikos prepared for a pulp mill deemed to have similar characteristics as NPNS was used to determine candidate chemicals of potential concern (COPC) for human health within the effluent anticipated to be produced by NPNS. The initial list had 39+ compounds listed which was reduced to four identified in Section 9.2.4.2. *"The outcome of the screening approach to identify substances that may accumulate in fish was a greatly reduced list of candidate COPCs. The final COPCs selected in the Toxikos HHRA study were: Cadmium, Mercury, Selenium, polychlorinated dibenzo-p-dioxins and dibenzofurans (PCDD/F)".* The Toxikos report indicated that "*PCDD/F was included due to regulatory and public concerns only, as it was noted there is no technical justification to include PCDD/F in effluent from an ECF mill…*". No information on projected levels of these metals or PCDD/F were provided in the EA so it is not possible to compare them to known LC50s in American lobster larvae for cadmium, mercury, and copper.

There are studies (see Pulp Mill Effluent Effects on Crustacean Health, this report) describing adverse effects of metals, particularly cadmium, on crustacean health with respect to moulting, reproduction and the glycemic/stress response. Given these studies, and the statement in the EA that these metals could accumulate in fish tissues, these metals could be considered COPC with regards to crustacean health.

CONCLUSIONS & RECOMMENDATIONS

Taken together, these studies suggest the potential for impact on crustacean health by several organic compounds (androgenic, estrogenic, antiestrogenic, antiandrogenic) which have suspected roles in impaired reproductive potential in finfish exposed to BKME. Metals such as cadmium that could be present in BKME are also recognised to impact growth and reproduction in crustaceans.

Due to the limited and dated information available regarding the potential for adverse effects on the health of the marine species of commercial interest, in particular growth and reproduction of crustaceans such as the American lobster and rock crab, upon exposure effluent to be produced by the proposed replacement effluent treatment facility at NPNS, further studies (acute and sublethal) are recommended.

March 8th, 2019

Dear Hon. Minister Miller:

Please find below concerns expressed by the Gulf Nova Scotia Fleet Planning Board, the PEI Fishermen's Association, the Maritime Fishermen's Union and Pictou Landing First Nation. The four groups together represent approximately 3,000 commercial fishermen who make their living in the Northumberland Strait.

Following a thorough review of Northern Pulp Nova Scotia's (NPNS) EA Registration Documents, both by us and by independent experts, we are extremely concerned with NPNS's proposal to pump effluent into the Northumberland Strait. As detailed below, as well as in the attached review by Dr. Battison and in the separately submitted expert review by SVS Ltd., NPNS's EA Registration Documents provide no assurance that marine life will not be harmed, or that our fishing industry and our way of life will not be irrevocably damaged.

We implore you to reject NPNS's proposal as presented and require NPNS to file a **thorough and rigorous Environmental Assessment Report, per subsection 13(1)(d) of the Environmental Assessment Regulations,** given the project's high risk of environmental effects. Failing this, the lack of sufficient information in NPNS's proposal on the impacts of the effluent on marine life and the health of the Northumberland Strait requires that you, at a minimum, deem the Registration Documents as insufficient and require more information, per subsection 13(1)(a) of the Environmental Assessment Regulations.

In addition to the concerns expressed below, please find attached Dr. Andrea Battison's review of the EA registration documents from an animal health perspective with a focus on crustaceans (Appendix A), along with Dr. Battison's list of publications (Appendix B). Also attached are documents obtained through FOIPOP requests and are referenced in the comments below (Appendix C). Furthermore, SVS Ltd. is submitting an expert review of the NPNS EA Registration Document under separate cover. SVS Ltd. was contracted by several fishermen's organizations to conduct an independent expert review of NPNS's new ETF proposal.

Fishing Industry's Concerns with Northern Pulp's EA Registration Document:

1. ***EA Registration Document fails to assess potential impact of effluent on crustaceans and other marine life.***

In her February 25, 2019 review (submitted separately), veterinarian Dr. Battison notes that with respect to the potential sublethal effects of exposure of crustaceans to NPNS's pulp mill effluent, NPNS relied on studies that "were limited in scope, used BKME different from that anticipated to be produced by the NPNS, and did not include sublethal toxicity or generational testing."

Additionally, Dr. Battison notes that "anticipated levels of [chemicals of potential concern] in the effluent are not provided in the EA, precluding assessment of toxicity to crustaceans…."

Dr. Battison concludes that,

> *Given the limited, and often dated, information available regarding the potential for adverse effects on the health, in particular growth (moulting) and reproduction, of marine species of commercial interest such as the American lobster and rock crab, upon exposure to the mill effluent to be produced by the proposed facility at NPNS, further studies (acute, sublethal, and generational) are recommended.*

Furthermore, the EA Registration Document fails to explain how NPNS will improve upon the Cycle 7 EEM Results regarding sublethal toxicity testing, which indicated that "there are chronic effects seen in laboratory test species at relatively low effluent concentrations…" (Appendix J, page 144).

Moreover, NPNS's own EA consultant, Dillon Consulting, recommended to NPNS in a February 14th 2018 letter that,

> *Conducting research on lobster larvae, … needs to be completed to demonstrate to regulators that these were properly considered and stakeholder concerns are being addressed as much as reasonable possible…. The level of stakeholder (commercial fishers) concern regarding lobsters necessitates the need for increased scientific understandings…. (FOIPOP 2018-07644-TIR2, page 476 – 479, attached in Appendix C, pages 1 - 4).*

Despite this recommendation from NPNS's own consultant, NPNS failed to carry out this research.

RECOMMENDATION 1: The Minister cannot accept the EA Registration Document as submitted given the effluent's potential harm to crustaceans and other marine life and given the lack of information to demonstrate whether this harm is negligible or significant.

2. ***NPNS's proposal to test effluent toxicity sometime within 24 months after the new ETF is operational (Appendix H, page 90) presents an unacceptable risk of significant harm to marine life.***

NPNS fails to indicate how it will mitigate negative impacts of the effluent on marine life that may occur before effluent testing is conducted. Given that NPNS has failed to disclose what the effluent leaving the new ETF will contain, forgoing monitoring of the effluent for up to 24 months poses an unacceptable

risk to marine life in the Strait. If effluent contains chemicals of concern that bioaccumulate in marine life, NPNS's proposed testing of the effluent may be too late to stop or mitigate the potential harm these chemicals present.

RECOMMENDATION 2: The Minister cannot accept the EA Registration Document as submitted because NPNS's proposal to test effluent toxicity sometime within 24 months after NPNS starts pumping effluent into the Northumberland Strait presents too high of an unmitigable risk to marine life and the fishing industry.

3. NPNS presented misleading statements to the public about the quality of effluent to be discharged from the proposed ETF, thereby compromising NPNS's public engagement process.

NPNS repeatedly made public statements to the effect that the effluent from the proposed ETF would be no worse than the effluent currently entering Northumberland Strait. For example:

- In a letter to the Town of Westville obtained through a FOIPOP request, NPNS's Director of Corporate Communications wrote "Northern Pulp has been releasing effluent into the Northumberland Strait for five decades. … Treated effluent that will be discharged under the proposed new design will see an even greater improvement…" (FOIPOP 2018-07644-TIR4, page 1104 – 1105, attached in Appendix C, pages 5 - 6).

- In a letter to Advocate News, November 24th 2017, NPNS's Director of Corporate Communications wrote "… Treated effluent has been discharged into the Northumberland Strait for 50 years; it is important to recognize that current effluent discharge into the region has not impacted fishing activities nor will it in the future." (FOIPOP 2018-07644-TIR5, page 1175 – 1177, attached in Appendix C, pages 7 - 9).

- In a letter to CBC reporters, November 15th 2017, NPNS's Director of Corporate Communications wrote the following response to a reporter's question "Are [the fishermen] right to be concerned?": "Treated effluent has been flowing through Boat Harbour and into the Northumberland Strait for over 50 years. The new treatment facility and diffused outfall <u>will reduce the impact on the Strait</u>. …" (FOIPOP 2018-07644-TIR5, page 1268 – 1271, attached in Appendix C, pages 10 -13) (emphasis added).

- In a letter to NPNS's EA consultant company Dillon Consulting Ltd., November 26, 2017, NPNS wrote: "… mark the existing outfall clearly on the map with a thick red line and put a sentence on the outfall page that says something like 'New outfall and diffuser located xx nautical miles from the existing outfall … We want the NB and PEI fishermen to clearly see it is there already." (FOIPOP 2018-07644-TIR5, page 1170 – 1171, attached in Appendix C, pages 14 - 15).

Moreover, NPNS's message that the new ETF will not increase impact on the Strait was echoed in Minister of Environment (as he was then) Iain Rankin's form letter sent to citizens concerned with the proposed ETF. He wrote in a January 18, 2018 letter: "… I am sure you are aware that effluent from the pulp mill has been treated by the Boat Harbour effluent treatment facility and then discharged into the

Northumberland Strait for the last 50 years. …" (FOIPOP 2018-06097-ENV, page 88, attached as Appendix C).

In stark contrast to these statement to the public through the media, internal statements within NPNS indicated that NPNS believed that the effluent from the new system would be "worse" that the effluent currently entering the Northumberland Strait. For example:

- In a letter to NPNS's EA consultant Dillon Consulting Ltd., NPNS's Technical Manager stated "Some say effluent quality will be worse than today because of all the polishing that is happening across the BH basin – and they are correct to some extent…" (FOIPOP 2018-07644-TIR4, page 1037 – 1041, attached in Appendix C, pages 17 - 20).

- In a letter to Gary Porter, senior employee with NS's Department of Transportation and Infrastructure Renewal, November 15th 2017, NPNS's Technical Manager stated "Right now mill has BH as large buffer zone, so effluent at point C is not comparable to new effluent. Need to compare to Point D or speak to difference between current point C and D. … [Consultant] KSH study that says AST [activated sludge treatment / proposed for new ETF] quality not significantly different than ASB [aerated stabilization basin, ie, Boat Harbour / current ETF]." (FOIPOP 2018-07644-TIR5, page 1274 – 1277, attached in Appendix C, pages 21 - 24).

- In a 2014 report by KSH consultants commissioned by NPNS, KSH states: "A large, natural final polishing/stabilization basin follows prior to release to the Northumberland Straight [sic]. … Point C of the effluent treatment system also benefits from the settling effect of Boat Harbour prior to Point D, so the impact on marine environments is even less pronounced." (FOIPOP 2018-07644-TIR6, page 1815 and 1825, attached in Appendix C, pages 25 - 26).

Given that NPNS acknowledged that the effluent to be released into the Northumberland Strait might be worse than they currently release into the Strait via Boat Harbour, NPNS's statements to the public that the effluent from the new ETF would be better or at least no worse are disingenuous and misleading and thereby compromised NPNS's public engagement process. There is no way to know what concerns the public may have expressed if the public had been given the full account of the relative quality of the effluent to be discharged from the proposed ETF.

RECOMMENDATION 3: The Minister cannot accept the EA Registration Document as submitted because NPNS compromised their public engagement process by providing misleading statements to the public about the relative quality of the effluent to be discharged into the Northumberland Strait from the proposed ETF.

4. NPNS has not demonstrated how the proposed ETF will accomplish the "polishing" effect on the effluent currently achieved through the 25 – 30 day settling in Boat Harbour before released into the Northumberland Strait.

The EA Registration Document notes that NPNS's effluent currently undergoes a "polishing" effect thanks to the 25 to 30 day settling period in Boat Harbour before the effluent reaches the Strait (Appendix J, page 23). However, the Document fails to describe how the proposed ETF will provide for

these same effluent quality benefits, or whether the lack of a "polishing" effect could cause significant environmental impacts.

Furthermore, the EA Registration Document (Appendix I4, page 24) also notes that the 2017 yearly average test results for TSS (Total Suspended Solids), BOD (Biochemical Oxygen Demand) and COD (Chemical Oxygen Demand) at point C were 1563, 1300 and 36,506 kg/day respectively, and that the values for these parameters at Point D were 775, 792, and 34,250 kg/day, respectively. These results indicate that TSS is 2 times larger at Point C than at Point D, that BOD is 1.6 times larger at Point C than at Point D, and that COD is 1.07 times larger at Point C than at Point D. The EA Registration Document fails to indicate how the advantages in reduced TSS, COD and BOD due to Boat Harbour will be achieved in the proposed ETF, or whether increased TSS, COD and BOD relative to Point D will have a negative and significant impact on the environment.

RECOMMENDATION 4: The Minister cannot accept the EA Registration Document as submitted because NPNS fails to demonstrate whether the lack of "polishing" effect and reductions in TSS, BOD and COD currently achieved by the settling time in Boat Harbour will cause significant environmental impacts, or whether the "polishing" and TSS, BOD and COD reduction effect will be achieved through other means in the proposed ETF.

5. NPNS fails to describe what the effluent will be composed of when it is released into the Northumberland Strait via the proposed ETF.

NPNS notes in the EA Registration Document that it rejected the possibility of discharging effluent into Pictou Harbour due to "the accumulation and increasing concentration of residual contaminants contained in the treated effluent, over time" (page 68). NPNS fails to describe what the "residual contaminants" in the treated effluent will be. It is impossible to determine the extent of harmful impacts on the environment that may occur given this lack of information.

RECOMMENDATION 5: The Minister cannot accept the EA Registration Document as submitted because NPNS fails to provide information about what potentially harmful components will be contained in the effluent.

6. NPNS failed to demonstrate that ice scour will not damage the pipeline and/or the diffusers.

The EA Registration Documents indicate that the pipeline route to Pictou Harbour was abandoned due to risk of ice scour damage (pages 47 and 70), yet the Documents fails to demonstrate that ice scour risk will be negligible at the Caribou Harbour site. Appendix E notes that "… an outfall pipe is proposed to be extended parallel to the ferry route to a deeper water location that might help avoid potential issues of ice scour" (page 9) [emphasis added].

Given that Northumberland Strait is ice-bound for a significant portion of the year, a compromised pipe and/or diffuser could result in a large amount of effluent released in an unplanned manner for a months-long duration before the problem is identified and fixed, potentially resulting in significant environmental impacts.

RECOMMENDATION 6: The Minister cannot accept the EA Registration Document as submitted because NPNS fails to provide sufficient evidence that ice scour will not compromise the integrity and function of the pipeline and the diffusers.

7. NPNS fails to explain how it will deal with its effluent between February 1, 2020 and the date by which the new ETF is operational.

The EA Registration Document indicates that the new ETF will not be operational by the January 31, 2020 deadline to close Boat Harbour (page 48). Yet, the Document fails to provide a plan for the intervening time between the closure of Boat Harbour and commencement of the new ETF. Without such a plan, the proposal lacks an air of reality. Furthermore, NPNS's plan for dealing with its effluent between February 1st 2020 and the commencement date of the new system could have significant environmental impacts; these impacts cannot be evaluated in the absence of a plan from NPNS.

RECOMMENDATION 7: The Minister cannot accept the EA Registration Document as submitted because NPNS fails to provide a plan for its effluent for the time between February 1, 2020 and the commencement of the new ETF.

8. NPNS fails to respond to Nova Scotia Environment's requirement to address all potential substances of concern, not just those outlined in the Federal Pulp and Paper Effluent Regulations.

In a letter from Nova Scotia Environment to NPNS's General Manager on June 14th 2017, NSE issued the following requirement to NPNS, at NPNS's request, with the subject line "Minimum Requirements of a Receiving Water Study":

> *… The mixing zone principle does not apply to hazardous wastes or dangerous goods. Mixing zones also do not apply to bio-accumulative or persistence [sic] substances and despite the allowance of a mixing zone, effluent shall not be acutely toxic. It should be noted that in this particular case, a receiving water study must address all potential substances of concern not limited to those outlined in the Federal Pulp & Paper Effluent Regulations.*
>
> *… In order to protect important aquatic communities … no conditions within the mixing zone will be permitted which:*
>
> *a. are acutely lethal to aquatic life;*
>
> *b. cause irreversible responses which could result in detrimental post-exposure effects;*
>
> *c. result in bioconcentration of toxic materials which are harmful to the organism or its consumer;*
>
> *d. attract organisms to the mixing zones, resulting in a prolonged exposure;*
>
> *e. create a barrier to the migration of fish or other aquatic life.*

… Mixing zones should not impinge upon … important fish spawning and/or fishing areas.

… When background water quality conditions at a proposed mixing zone site are degraded, effluent discharge requirements established must ensure, at the very least, that background water quality is not further degraded.

The Department requires enough information to ensure each of the above concerns is adequately addressed. Specifically including but not limited to:

- *information about the effluent (substances of potential concern, volumes, etc.);*
- *information about the receiving water (physical characteristics, size, upstream and downstream water quality); …*

The information provided to the Department should include one year's worth of effluent characterization data. … Water quality considerations take precedence when contaminant discharges exceed the assimilative capacity of the receiving waters, even if the discharged loadings are within the treatment technology based effluent requirements based on the guidelines, regulations or policies. Receiving-water based effluent requirements also take precedence when ambient levels of contaminants are above acceptable levels. …

All effluent discharges must not be acutely lethal. (FOIPOP 2018-07644-TIR5, page 1422 – 1424, attached in Appendix C, pages 28 - 31)

The EA Registration Document fails to respond to the requirements detailed in NSE's letter to NPNS. The Document fails to provide detailed information about the effluent, fails to demonstrate how the mixing zone will not impinge upon important fish spawning and fishing areas, and fails to provide one year's worth of effluent characterization data. Without such information, the Minister cannot make an informed decision on whether the effluent will be acutely lethal to aquatic life, cause irreversible responses which could result in detrimental post-exposure effects, or result in bioaccumulation of toxic materials, among other potential impacts.

RECOMMENDATION 8: The Minister cannot accept the EA Registration Document as submitted because NPNS fails to respond to Nova Scotia Environment's specific information requirements to be included in the Document and therefore the Minister does not have sufficient information to determine whether the project will result in significant adverse environmental impacts.

All of the above is respectfully submitted to the Nova Scotia Minister of Environment, the Honourable Margaret Miller, within the 30-day public comment period with respect to Northern Pulp Nova Scotia's proposed Effluent Treatment Facility.

Sincerely,

Prince Edward Island Fishermen's Association, President

Maritime Fishermen's Union, President

Gulf Nova Scotia Fleet Planning Board, President

Project: replacement_effluent_treatment_facility_project Comments: I have great concern regarding the replacement effluent treatment facility project. I believe, at the very least, a federal assessment is required and necessary. o Northern Pulpâ?Ts submission does not prove a lack of significant risk, and is missing critical data on many issues. o There is insufficient evidence to know exactly how broad any damage might be. The companyâ?Ts claim that damage will be â?ominimalâ? is not credible and should not be accepted. o Fisheries, tourism and outdoor recreation are important economic factors and should not be put at risk. o The United Nations Declaration on the Rights of Indigenous Peoples requires not just consultation, but consent by the local Indigenous population. Pictou Landing First Nation is opposed to this proposal. o A 30-day comment period on the companyâ?Ts 2,000-page submission is completely inadequate. o Oceans need more protection, not less. Environmental security outweighs the risk of job loss. New jobs can and will be created if necessary. Thank you, Name: Email: @gmail.com Address:

Subject: In support of Northern Pulp"s EA application
Date: March 8, 2019 11:25:32 PM

I am writing in support of the Environmental Assessment application submitted by Northern Pulp for its new treatment facility.

A lot has been said about Northern Pulp and its impact on the local community. I stand in agreement with many, including Unifor, that Boat Harbour must close and be cleaned up to respect Pictou Landing First Nations people and their land. I also know there are many positives about having 300 good-paying jobs in Pictou, supporting thousands more across Nova Scotia, particularly in rural communities.

The Nova Scotia Environment Act is an essential piece of legislation designed to protect our shared environment and guide our economic development. The Act rightly spells out its purpose through a set of principles for sustainable development that should guide its application, including:

------> The linkage between economic and environmental issues, recognizing that long-term economic prosperity depends upon sound environmental management and that effective environmental protection depends on a strong economy.

In this situation, science should determine the best path forward. Nova Scotia, along with the rest of Canada, has among the highest global standards for environmental stewardship in the forestry sector.

The job of government and every person we elect to represent us in government is to find the best way forward when there are many competing and sometimes opposing interests. Communities across Canada manage to find a fair balance where good mill jobs coexist with a prosperous fishing industry and thriving communities.

We can and must find this balance for Pictou. There is a lot at stake: jobs, the environment, and respect for First Nations. We can and must find a solution that supports all three.

Thank you.

RE: Northern Pulp Nova Scotia - Environmental Assessment Registration Document-Replacement Effluent Treatment Facility

Please see the following document in response to the Environmental Assessment of Northern Pulp's Effluent Replacement Project. The following document will focus on some major concerns of the underwater portion of the proposed pipe and the site-specific characteristics of the seafloor along the proposed route. I am a commercial fisher and harvest lobster, rock crab, and herring from the waters directly surrounding the proposed pipe route and outfall location. I also have a background in structural engineering and have worked on various projects throughout the Maritimes assisting in both the structural design and geotechnical investigation of various structures. This submission will include a combination of site-specific observations and the effects it will have on the structural integrity of the pipe.

Sincerely,

1.0 SEAFLOOR CHARACTERISTICS OF PROPOSED ROUTE

1.1 Effluent Effects Rock Crab Population

Inside Caribou harbour consists mainly of shallow soft sand and mud bottom with portions of broken hard bottom. Such seafloor characteristics create a favourable environment for the rock crab population to flourish. While harvesting rock crab throughout LFA 26A fishers have observed that this inlet presents optimal conditions for juvenile and female rock crabs. If you place traps within the harbour (south/southwest of Munros Island or directly east of the ferry terminal) the majority of the harvested catch appears to consist of small juvenile crab including a high percentage of females. As you move out of the harbour along the proposed pipe route and along the shore east and west the percentage of harvestable rock crab (a rock crab of legal size) within the catch appears to significantly increase. Traps placed further offshore in deeper waters tend to have a catch rate with the majority of the catch consisting of large harvestable crabs with very few undersized crabs. Over the years all of the above has remained consistent and local fishers have concluded that the Caribou harbour acts as a breeding ground and an optimal environment for juvenile rock crab to mature before moving to deeper waters. This raises the major concern of what effect will this effluent have on these juvenile rock crab and the rock crab population as a whole? Not to mention the chain reaction that would occur throughout other species including lobster whose diet consists of a large percentage of rock crab (Fisheries & Oceans Canada, 2013).

1.2 Effects of Site Specifics on Structural Integrity of the Pipe

The marine portion of Northern Pulps pipeline design consists of approximately 4 kilometers of 36” high density polyethylene (HDPE) pipe that will be weighted with concrete ballast and placed in a 3 m trench (providing approximately 2 m of cover to the top of pipe) and will be backfilled with armour stone (Appendix F, Northern Pulp, 2019).

The pipeline location proposed by Northern Pulp presents various challenges that must be addressed to ensure the structural integrity of the pipe. As previously stated, the bottom has been observed by fishers to consist of soft sand and mud bottom with small pockets of hard bottom. With no geotechnical investigation carried out by any of Northern Pulps consultants it is unknown how deep the soft bottom continues. This raises the concern of non-uniform settlement of the soil that will be supporting the pipe. Due to the pipe being placed in a pre-dug trench during the construction phase it is likely that the pipe will experience increased installation deflections due to the trench quickly being filled in with sand due to wave and tidal action, thus creating discrepancies between design pipe elevations and as built pipe elevations. The pipe is also likely to experience increased in-service deflections over time due to the pockets of hard bottom creating a point of solid support while large portions of soft bottom allow for settlement and pipe sag. These deflections will induce increased compressive and tensile bending stresses within the pipe wall resulting in bending strains. The design code aims to limit these strains and the geometric stability of the pipe by setting ring deflection limits of 7.5%. As deflections increase beyond this point geometric stability is eventually lost and the crown of the pipe will begin to flatten and eventually

reverse leading to reverse curvature collapse of the pipe Figure 1 shows observed pipe deformation patterns that lead to failure due to increased pipe deflections (Plastic Pipe Institute, 2014).

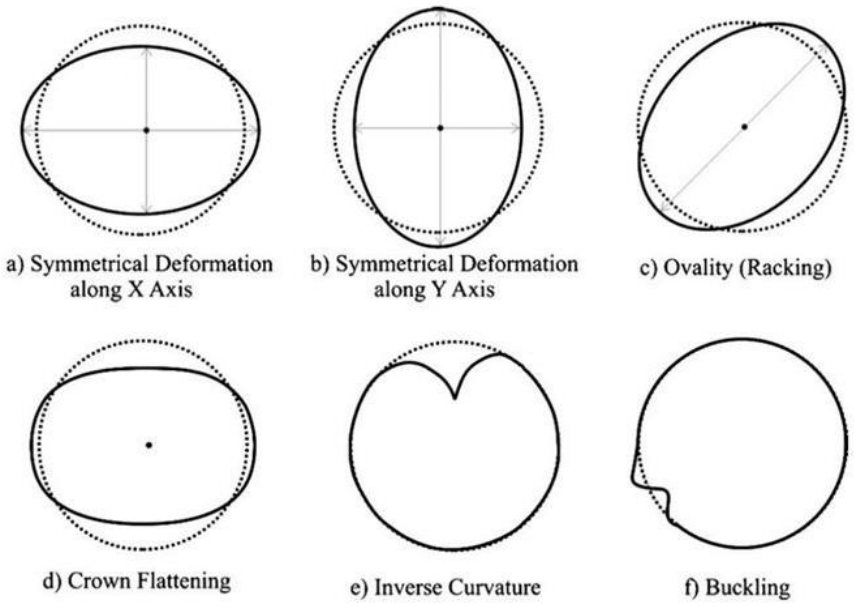

Figure 1: Observed deformations of installed HDPE pipelines (Motahari & Abolmaali, 2010)

Figure 1 is from a study published in the Journal of Transportation Engineers of the American Society of Civil Engineers (ASCE). The study included structural monitoring with video and laser surveillance of over 15,000ft (96 pipelines) of buried HDPE pipe across the USA. It was concluded that the majority of pipelines had actual deformations in excess of design code limits (Motahari & Abolmaali, 2010). This study gives great insight into the possible repercussions of not accurately modeling induced strains in buried HDPE pipes.

Due to the cyclical nature of the tidal forces and wave action these induced stresses combined with ice loads over time could present fatigue stress issues. Although HDPE pipes are extremely flexible making them well suited to bend and adhere to the seafloor, cyclical loading has the potential to cause failure if the site-specific loadings on the pipe are not properly addressed. "One of the causes for failures of HDPE pipes is fatigue which is the result of pipes being subjected to cyclic loading, such as internal pressure, weight loads or external loadings on buried pipes, which generate stress in different directions: circumferential, longitudinal and radial." (P. 600, Djebli et al., 2014). To accurately determine these site-specific loads, various data is required including accurate geotechnical site investigation with borehole results, hydrographic site surveys including bottom type/depths, potential ice scours, and site observations of ice conditions. It should be noted that none of these are present in Northern Pulp's submission.

Of all the loads the pipe will experience, ice loads present that largest risk to the structural integrity of the pipe. Potential failure of the pipe due to ice could occur from one of two mechanisms: 1) Direct impact causing a ductile failure (high amount of stress over a relatively short time), 2) Cyclical loading causing a brittle failure (stress levels lower than the mechanical strength of the

material induced repeatitly over a relatively long time) (Zhang, 2005). Brittle failure due to ice impact could occur if any of the following project tasks are neglected: complete a site survey of ice conditions, complete a hydrographic survey depicting any potential ice scours, bury pipe at an adequate distance to account for extreme ice event. Although Northern Pulp shows a pipe buried with cover of approximately 2 meters, they have not completed any of the pre-design field work required to ensure that the pipe is not at risk of failure. When determining extreme ice scouring events, it is also recommended that ice scour surveys be carried out more than once, spaced out over time to gain an accurate depiction of the ice and seafloor interaction (C-Core, 2004). Grounding models such as the one created for a tunnel project crossing the Strait of Belle Isle, Newfoundland can also be carried out to gain insight into ice activity in a given region (C-Core, 2004). The soft soil and shallow design depth of the pipe (approximately 2 meters) also poses concerns for ice and seafloor interaction. If large ice accumulation was present and gouged the seafloor to the unknown depths of the soft bottom there would be no evidence of such gouges once the ice had melted as the sand would infill the gouges within a couple tide cycles. Figure 2 and Figure 3 are a photo's taken March 4th, 2019 from the Caribou light house, the PEI ferry can be seen docked in the background.

Figure 2: Ice southeast of Caribou lighthouse along proposed pipe route (March 4th, 2019)

This photo shows extensive ice directly over the proposed pipe route. Locations where water depths are as shallow as 1 meter have ice piles of 3-4-meter heights above sea level. It is not unlikely to conclude from these photos alone that potential for ice impact at a depth of 2m below seafloor bottom in a soft bottom is a very real possibility that could lead to a ductile failure resulting in the catastrophic event of premature released effluent into the Caribou harbour. Figure 3 shows more ice further north along proposed pipe route.

Figure 3: Ice east of Caribou lighthouse along proposed pipe route (March 4th, 2019)

now retired, fished the waters surrounding the proposed pipe location for 55 years. Along with other species fished lobsters along the shores of Caribou Island. He recalls one winter when ice conditions were at their peak, one of his most lucrative lobster spots was completely wiped out by the ice. North of Black Point the bottom consisted of dense hard bottom with drastic elevation changes in the bottom including a large trench where lobsters could always be found. The following spring the rock bottom had been completely changed and the trench had been filled in.

a long-time fishermen and a commercial diver in the area for 25 years have also seen the power of the ice in the area. One spring could not seem to get his traps boarded as they were tangled on something on the bottom. When dove to retrieve them a navigational marker buoy from PEI was found drove into the rock bottom by the ice.

3.0 RECIEVEING WATER STUDY

Events that would be catastrophic to the marine ecosystems include: 1) Structural failure of the pipe causing effluent to be released prematurely of the discharge location. 2) Errors in the receiving water study including tides, water flow, mixing characteristics at discharge location, lack of consideration for climate change effects will have on mixing characteristics.

The shallow soft bottom that extends south of the Caribou lighthouse combined with Munroe's Island extruding westward creates a bottleneck effect for the water currents. This bottleneck effect is also accelerated by the water moving in from deep waters to shallow waters on a rising tide.

These physical characteristics create accelerated tides and wave action, across the proposed location. These conditions combined with a prevailing north wind can cause water to swell into the harbour and hold waters in the harbour longer on a rising tide this gives the harbour very poor flushing characteristics. If there were a failure in the pipe at a location prior to the diffusers there would be no chance of meeting the dilution standards. The same could be said about the diffuser location if there is any variability in the water/mixing properties that were used in the receiving water study. Although computer modelling can give great insight into complex problems performing thousands of iterations and time steps in the matter of seconds, the results are only as good as the variables that were entered into the model. When dealing with a project with environmental consequences as catastrophic as this, each variable of tidal data, water depths, salinity, mixing characteristics etc. must be observed and calculated in a timely manner to ensure the level of confidence of the model is extremely high.

In near field portion of the receiving water study Stantec states "No historical water quality data are available for Northumberland Strait around the CH-B location. Data from the neighbouring Pictou Road (Stantec, 2017) located about 6 km southeast were used." (Stantec, 2018). While in the far field portion of the study they simply extended the boundaries of the previous model created for the previous outfall location in the original study that was completed for Pictou Harbour (Stantec, 2017). I will not attempt to touch on the technical data within the receiving waters study as I do not have the educational background to do so. I will however pose the following questions: Has adequate field investigations been carried out to ensure the results of these models are correct? Is stating there was no historical data thus we used data from our previously studied location sufficient? Should actual water sampling have been carried out at the actual location? Is this project being fast tracked? The study concludes that "The effluent discharged at the CH-B location is predicted to be dispersed and transported predominantly with offshore currents in the northwest and southeast directions. The effluent intrusion into Caribou Harbour is predicted to be minimum." (P.27 Stantec 2018). With what level of confidence can they make this statement while some data was simply pulled from the original location of Pictou Harbour? Have they modelled the bottleneck effect that all fishermen are aware of?

4.0 CONCLUSIONS & RECOMMMENDATIONS

Due to the lack of detail presented concerning site-specific data of various elements of the project, the minister must request an environmental assessment report. The report should include a geotechnical investigation, hydrographic survey and further investigations detailing ice presence. Pipe deformation issues should be addressed and a study must be conducted to ensure that direct ice impact will not occur. A detailed tidal study should be carried out to ensure that the effluent will not intrude into Caribou harbour severely effecting the marine ecosystem.

TO: Environmental Assessment Branch, Nova Scotia Environment, EA@novascotia.ca

Dear Minister Miller:

I am writing to you on behalf of the South Shore Chapter of the Council of Canadians. We are part of the national Council of Canadians, Canada's largest citizen advocacy organization. Our chapter promotes education, discussion and action on significant issues affecting our lives.

We call on the Nova Scotia government to reject the proposed Northern Pulp Replacement Effluent Treatment Facility Project based on the following key points which have been outlined by the groups based in the communities most affected by this issue.

Northern Pulp has been unable to prove that there will not be significant risk. Their claim that damage will be 'minimal' is not good enough. We cannot allow this company to put our fisheries, tourism and outdoor recreation industries at risk.

Northern Pulp has failed to meet the requirement of consent from the local Indigenous population. Pictou Landing First Nation is opposed to this proposal.

At a time when Nova Scotia has paid lip service to a just transition to a sustainable economy, and at a time when the IPCC report issued in 2018 has warned us that we have only 11 years to curb GHG emissions, this path is foolhardy for our province to pursue. We need to take all available steps to protect our ocean and our province.

We call on the Government of Nova Scotia to reject the proposed Northern Pulp Replacement Effluent Treatment Facility Project. We fully support the closure of the effluent treatment facility in Boat Harbour on schedule.

(for South Shore Chapter of the Council of Canadians)

Subject: In support of Northern Pulp"s EA application
Date: March 9, 2019 8:52:19 AM

I am writing in support of the Environmental Assessment application submitted by Northern Pulp for its new treatment facility.

A lot has been said about Northern Pulp and its impact on the local community. I stand in agreement with many, including Unifor, that Boat Harbour must close and be cleaned up to respect Pictou Landing First Nations people and their land. I also know there are many positives about having 300 good-paying jobs in Pictou, supporting thousands more across Nova Scotia, particularly in rural communities.

The Nova Scotia Environment Act is an essential piece of legislation designed to protect our shared environment and guide our economic development. The Act rightly spells out its purpose through a set of principles for sustainable development that should guide its application, including:

------> The linkage between economic and environmental issues, recognizing that long-term economic prosperity depends upon sound environmental management and that effective environmental protection depends on a strong economy.

In this situation, science should determine the best path forward. Nova Scotia, along with the rest of Canada, has among the highest global standards for environmental stewardship in the forestry sector.

The job of government and every person we elect to represent us in government is to find the best way forward when there are many competing and sometimes opposing interests. Communities across Canada manage to find a fair balance where good mill jobs coexist with a prosperous fishing industry and thriving communities.

We can and must find this balance for Pictou. There is a lot at stake: jobs, the environment, and respect for First Nations. We can and must find a solution that supports all three.

Thank you.

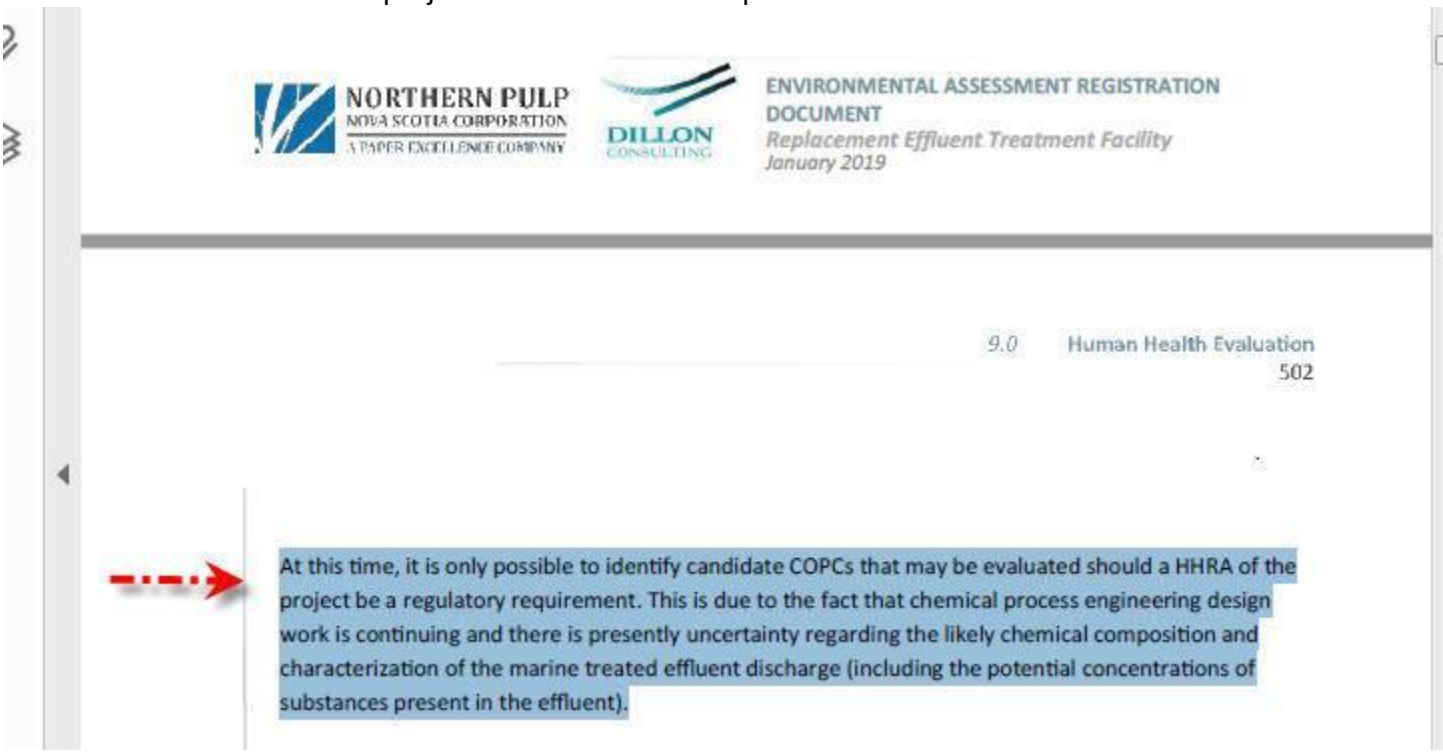
RE: Northern Pulp Effluent Treatment Facility

Good morning,

I am writing to you today to express my concerns regarding the Northern Pulp Effluent Treatment Facility with special trepidation regarding the indication that effluent from this facility will be pumped via a pipeline that passes by the Town of Pictou's watershed land and then dumped into the Northumberland Straight.

I am a resident of Pictou having moved here over years ago. I have spent much of my career in the business world and one component of my work has been establishing whether the RISKS associated with a project are acceptable and assuring that if the risks are greater than the outcome, a project will not move forward. I believe in the case of a pipe being constructed to carry effluent – the chemical makeup of which is not 100% known (according to the Environmental Assessment document submitted by Northern Pulp) - creates a scenario where the risks associated with this project ARE NOT worth the potential outcome.



NORTHERN PULP
NOVA SCOTIA CORPORATION
A PAPER EXCELLENCE COMPANY

DILLON CONSULTING

ENVIRONMENTAL ASSESSMENT REGISTRATION DOCUMENT
Replacement Effluent Treatment Facility
January 2019

9.0 Human Health Evaluation
502

At this time, it is only possible to identify candidate COPCs that may be evaluated should a HHRA of the project be a regulatory requirement. This is due to the fact that chemical process engineering design work is continuing and there is presently uncertainty regarding the likely chemical composition and characterization of the marine treated effluent discharge (including the potential concentrations of substances present in the effluent).

From my perspective let's look at some of the parties that will be impacted by this project when something does go wrong – and looking at the history of this company (as well as previous owners), something will. The fact is that at times pipes leak and sometimes break. We have

been made aware of two leaks in the current system at Northern Pulp in the past several years. The conditions where a pipeline is installed, the person(s) installing the pipeline and the actual pipe itself are all subject to the real risk of leakage and potential environmental damage.

1. **Fisheries**
   The risks associated with this project include extensive damage to the ecosystem in the Northumberland Straight. This will directly impact the livelihoods of fishermen and fisherwomen in three provinces directly (Nova Scotia, New Brunswick and Prince Edward Island). This industry is a multi-billion-dollar business which exports seafood internationally. Just imagine what would happen if this pipe went in and the effluent is harmful to the marine life. Mad cow disease took decades to recovery from and it doesn't take much imagination to see what would happen to this industry.

   We have the most pristine cold waters. In 2017 the value of our seafood exports was $2.0 billion. Infrastructure at Halifax Stanfield Airport has begun to increase with holding areas for lobster and with 3-5 air cargo shipments to China per week, as well as flights to Seoul, Korea.

   Northern Pulp constantly talks about their “spin-off” jobs. Fisheries also has “spin-off” jobs – it is another product that requires the same structure to export. Let’s not forget those.

2. **Tourism**
   The Tourism sector also brings billions into this province mainly due to our clean oceans, beautiful beaches and magnificent scenery – not to mention the friendly people. Why would we want to put this at risk? Even taking into account the number of "spin-off" jobs Northern Pulp states, the RISK is not worth it. The Tourism industry employs thousands of people in Nova Scotia and has far more economical impact than the 277 jobs at Northern Pulp. This company is part of Paper Excellence who have a horrid record on the environment internationally.

   In addition, there is the “spin-off” revenue that is brought to the many cities and towns that the tourists visit – and spend their money. Nova Scotia is "**Canada's ocean playground**". If there is an incident in the waters of the Northumberland Straight, there will be no recovery.

3. **Local Real Estate Market**
   If such a break would occur, there is also the potential for the real estate market to die completely in this area of Nova Scotia - for homes and cottages. I personally will have to consider selling both my home in Pictou and my cottage on Cape John should a decision be made to move forward on this project. If and when there is a breach in the pipe effecting either the Pictou watershed or the Northumberland Straight, this would render both properties unsaleable and that is not a risk I am willing to take. I also expect that

should this occur, the Nova Scotia government will have liability to its citizens in this case – after all these would be preventable damages.

4. **Town of Pictou residents**
   Now that the plan has been filed, the matter of the pipe and where it is planned to be constructed and where it will dump the effluent is known. There are many better qualified people who can and I am sure will speak to the chemical nature of the effluent (what is known at least) however I can speak to the fact that the pipe is to be constructed close to the watershed for the Town of Pictou. We have just come to the point of having clean water in our town, thanks for grants from both the Federal and Provincial governments as well as rate adjustments to the town residents. This has been a multi-year and multi-million-dollar project and in NO WAY should any risk be taken with regards to clean water in our town.

   The Town of Pictou heard about this via the media, like everyone else. As a major stakeholder in this situation this is unacceptable and again finds Northern Pulp not true to their word. There has also been NO information sessions on this project held in the Town of Pictou which to me is quite telling.

5. **Pictou County residents**
   There is also the consideration of the quality of air. This part of the province has suffered enough regarding this – every citizen should be able to open their windows on a nice warm day and the reality here is that we can't. This should not be the case in Nova Scotia. It has greatly affected the businesses in our town – many who have left since visitors want no part of this.

   Several local medical doctors have recently written concerning the quality of the air here (John Krawczyk, MD ; Anne Kwasnik- Krawczyk, MD; Maurice Strasfeld, MD; Gerry Farrell, MD; and Catharina Felderhof, MD). Their full letter can be found at https://nsadvocate.org/2019/03/06/letter-northern-pulp-wealth-over-health/?fbclid=IwAR3JOvaYq1ncax-lvZNPzsv3P29IFunDd-qN6I7NQxCKGXSPKzvlhmhMvVs – however here is a brief excerpt regarding the particulate matter coming into the air from the pulp mill:

   > *"In 2013 the WHO declared PM 2.5 carcinogenic to humans. Once in the air it can stay in the air for days to weeks and it can travel hundreds to thousands of miles. The new precipitator installed on the recovery boiler addresses a percentage of the PM2.5. The main boiler has no precipitator, but has scrubbers. These mechanisms require constant maintenance to operate with high efficiency. The results of the operating efficiency should be transparent and made public and tested more frequently."*

I would also refer you to an article from Dalhousie University that was published earlier this week on the cancer-causing impact of the air emissions released from Northern Pulp, which can be found at https://www.halifaxexaminer.ca/province-house/dalhousie-researcher-breaks-silence-over-pulp-mills-cancer-causing-air-emissions/?fbclid=IwAR1vhmxpQra7s5kcivyS0NC9fJRiunR2399AcW-DTdPm_WPogPFhwjwag3I

As well, in the Environmental Assessment document, Northern Pulp used the Tasmania Pulp mill for comparison for part of the Human Health Evaluation

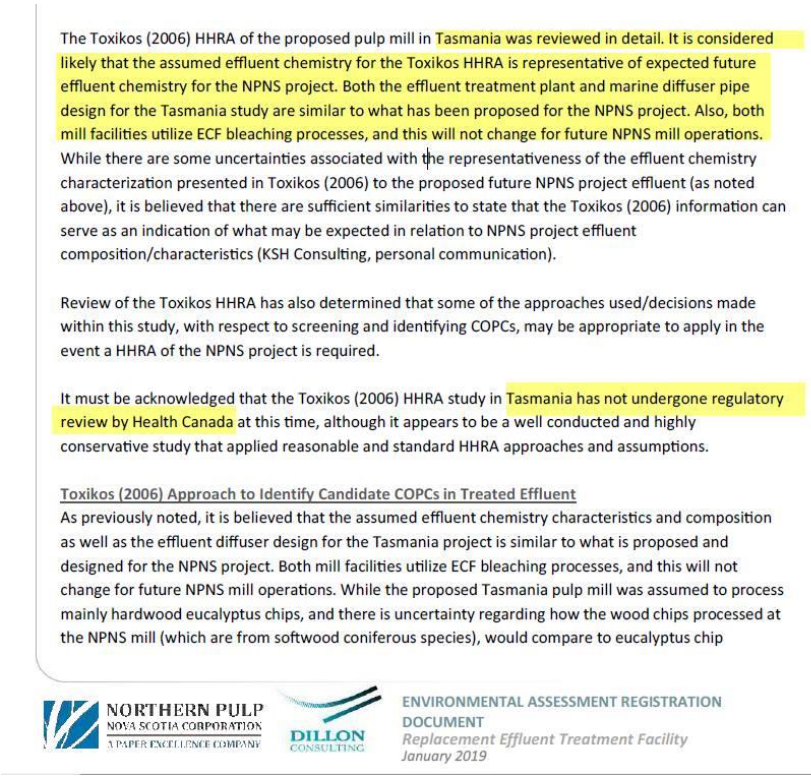
* It is important to note the Tasmania mill DID NOT open and faced many environmental challenges in court https://en.wikipedia.org/wiki/Bell_Bay_Pulp_Mill

* It also DID NOT undergo regulatory review by Health Canada

* There was no mention of their effluent facility technology

* It was using hardwood eucalyptus not softwood

From the EA:
"The Tasmania pulp mill process mainly hardwood eucalyptus chips. There is some uncertainty regarding how the wood chips processed at the NPNS mill, which are from softwood coniferous species, would compare to eucalyptus chip processing, with respect to potential effluent chemistry differences." EA. Section 9-15 page 492



The Toxikos (2006) HHRA of the proposed pulp mill in Tasmania was reviewed in detail. It is considered likely that the assumed effluent chemistry for the Toxikos HHRA is representative of expected future effluent chemistry for the NPNS project. Both the effluent treatment plant and marine diffuser pipe design for the Tasmania study are similar to what has been proposed for the NPNS project. Also, both mill facilities utilize ECF bleaching processes, and this will not change for future NPNS mill operations. While there are some uncertainties associated with the representativeness of the effluent chemistry characterization presented in Toxikos (2006) to the proposed future NPNS project effluent (as noted above), it is believed that there are sufficient similarities to state that the Toxikos (2006) information can serve as an indication of what may be expected in relation to NPNS project effluent composition/characteristics (KSH Consulting, personal communication).

Review of the Toxikos HHRA has also determined that some of the approaches used/decisions made within this study, with respect to screening and identifying COPCs, may be appropriate to apply in the event a HHRA of the NPNS project is required.

It must be acknowledged that the Toxikos (2006) HHRA study in Tasmania has not undergone regulatory review by Health Canada at this time, although it appears to be a well conducted and highly conservative study that applied reasonable and standard HHRA approaches and assumptions.

Toxikos (2006) Approach to Identify Candidate COPCs in Treated Effluent

As previously noted, it is believed that the assumed effluent chemistry characteristics and composition as well as the effluent diffuser design for the Tasmania project is similar to what is proposed and designed for the NPNS project. Both mill facilities utilize ECF bleaching processes, and this will not change for future NPNS mill operations. While the proposed Tasmania pulp mill was assumed to process mainly hardwood eucalyptus chips, and there is uncertainty regarding how the wood chips processed at the NPNS mill (which are from softwood coniferous species), would compare to eucalyptus chip

6. **Pictou Landing First Nations**
   The Boat Harbour situation which the people of the Pictou Landing First Nations have been dealing with for over 50 years must come to an end. This is one of the worst cases of Environmental Racism to occur in our county and it is well past time for it to come to an end. On that note, I do not believe any extension should be granted to Northern Pulp. The Boat Harbour Act was legislated in 2015 for closure on Jan 31, 2020. Northern Pulp did not file its Environmental Assessment to the Province of Nova Scotia until January 31, 2019 - only one year from the legislated closure - not enough time to get approval and start purchasing and construction to meet the deadline. Their plan should have been filed well before this.

   Nova Scotia has been standing proud with regards to its dealings with our First Nations and has made some great progress in recent years. This is the time to support the Pictou Landing First Nation people. Actions speak louder than words.

Summary

It is time to protect the environment and the people of Nova Scotia. It is time to stop corporate welfare in this province. – a Northern Pulp employee who has been speaking publicly on this matter (see CBC coverage on this topic) has indicated that his employer has "deep pockets". I would suggest if the mill had wanted to continue its operation here, those deep pockets could be used to create a closed-loop process where there is zero environmental impact (or close to it). I have heard arguments all about how it doesn't exist however if Northern Pulp can source studies on mills that have never opened, then surely they can discover the science to plan and implement a closed-loop solution.

In my opinion, current government can create a **new legacy** by doing the right thing here and ending the use of Boat Harbour and ensuring that another environmental disaster does not occur in the Northumberland Straight. #nopipe #noextension

Thank you for your time and consideration of my comments and concerns.

Pictou, Nova Scotia

Subject: Northern Pulp Effluent Treatment Facility Proposal
Date: March 9, 2019 9:41:08 AM
Attachments: Northern Pulp's Treatment Facility.docx

Sent from my iPad

March 8, 2019

Dear Nova Scotia Minister of Environment,

I am writing to you to express my concerns with Northern Pulp's Replacement Effluent Treatment Facility. Northern Pulp's proposal of putting a pipe, pumping unknown effluents into the Northumberland Strait, certainly requires more information and answers. Any risk to our fishery, tourism and the environment is a risk not worth taking. I strongly urge you to acquire all the scientific information needed to properly assess the affects that this "unknown" effluent will have on the lobster larvae, herring spawn and human life.

The mere fact that Northern Pulp has stated in their Environmental Assessment (EA document page 489) that "the effluent chemistry characteristics (including the specific substances present in treated effluent and their anticipated concentrations) will not be known with certainty until the project is operational" is concerning and needs further study. Pumping 62 to 90 million litres of this effluent per day into the Northumberland Strait will put our fisheries at risk. Northern Pulp has stated " the identified candidate COPC's in effluent are considered preliminary at this time", therefore, this proposal shows that there is a potential risk to the health of our beautiful Northumberland Strait. Thirty percent of Canada's fishery revenue comes from the Southern Gulf including the Northumberland Strait. The reputation of Canada's fishing industry is built on clean , pristine waters off our coastlines. A threat to this reputation is a risk to all of Canada's fishing industry. Any risk to our Strait and to the reputation of our fishing industry must be examined and studied until we know all the facts.

As a lifelong resident of Pictou I have enjoyed walking our beautiful beaches, especially Munroe's Island. The proposed pipe will be pumping unknown effluent not far from Munroe's Island which is one of Nova Scotia's unspoiled natural beauties and is a sanctuary for birds and wildlife. It is important to protect these delicate areas from environmental dangers. Tourists are drawn to Nova Scotia for its beautiful coastlines and beaches. I have sailed the Northumberland Strait fishing mackerel, lobster and have seen many whales and porpoises swimming in

our waters. Tourism is important for the economy of all Nova Scotians and this proposed pipe with its unknown dangers, effects and deadly consequences to our beautiful coastline places this important industry in jeopardy as well.

In conclusion, Northern Pulp's Replacement Treatment Facility Proposal has too many unanswered questions that will have devastating consequences for our Strait, fishing industry and all of Nova Scotia. I strongly urge you to do a full Environmental Assessment, the unknowns and risks are too many to ignore. Boat Harbour is proof of what happens when decisions are made without knowing all the risks, **when we know better, we should do better.** Do Not let our beautiful Northumberland Strait become the "new" Boat Harbour.

Sincerely,

@hotmail.com

Subject: Proposed Project Comments
Date: March 9, 2019 9:57:04 AM

Project: replacement_effluent_treatment_facility_project Comments: As a practising Engineer in Nova Scotia, Ive made my career in analyzing, minimizing and preparing for risk. As a general rule: the more unknowns that must be accounted for, the greater the risk. We cant forget that these same scientific arguments emerging from the latest batch of consultant reports paid for by Northern Pulp created our current environmental predicament at Boat Harbour and beyond. This mill wasnt supposed to destroy Boat Harbour, but it did. The airborne toxins werent supposed to elevate cancer levels to the highest per capita in the country... but they did. However, even if all this science somehow worked out, and we all came to an agreement that dumping 90 million litres of effluent into the lobster grounds was somehow a good idea, are you going to eat the lobsters? Is anyone going to eat the lobsters, knowing whats going on here? When the foaming agents start to settle on the beaches but someone in a lab coat tells you its fine, are you going to swim in the water? Even if taking this action didnt violate federal regulation and didnt scientifically remove everything good that this town has left, the perception will. To all environmental ministers involved, I implore you to make the right decision here. Name: Email: @hotmail.com

Re: Replacement Effluent Treatment Facility (ETF) Project for Northern Pulp

I am a resident of the Town of Pictou who is very concerned about Northern Pulp's Environmental Assessment (EA) application. After reviewing the company's application documentation, I remain wholeheartedly opposed to the proposal because i) many aspects of the proposal are inconsistent with the principles of sustainable development that are supposed to be protected with the *Environment Act,* ii) the information provided in the documentation is misleading, and iii) there is a lack of trust that, if approved, Nova Scotia Environment has the capacity to monitor and enforce compliance with regulations. Each of these points will be addressed separately below.

i) The proposal is inconsistent with the principles of sustainable development protected by the *Environment Act*.

The proposal is inconsistent with the principles of sustainable development that are supposed to be protected with the *Environment Act*. In particular, the absence of critical information in the application documentation suggests that the precautionary principle identified in Nova Scotia Environment's Guide to the Environment Act (https://www.novascotia.ca/nse/ea/docs/EAActGuide.pdf) ought to outweigh any other consideration. According to the precautionary principle, an activity whose effects are disputed or unknown should be avoided, and therefore, the proposal ought to be rejected because:

- The final characteristics of the effluent are admittedly **unknown** by Northern Pulp and will remain **uncertain** until the new treatment system is up and running as indicated in Section 9.0 Human Health Evaluation, page 502,

  > "there is presently uncertainty regarding the likely chemical composition and characterization of the marine treated effluent discharge (including the potential concentrations of substances in the effluent"

- The proposal does not include lobster larvae tests or tests on herring spawning grounds, thereby indicating these effects are **unknown**. This is a particularly glaring omission

given that these tests were specifically requested by those directly affected by potential negative effects of the effluent.

- The proposal does not mention the known mercury contamination in the soil and bedrock proximal to the proposed new treatment plant and basins, nor does it acknowledge the potential for disturbing the mercury contamination during construction. (Baxter, J., The Canso Chemicals mystery: With the chemical plant long gone, why is the company still alive? And what about all that mercury pollution?, *Halifax Examiner,* March 7, 2019, https://www.halifaxexaminer.ca/province-house/the-canso-chemicals-mystery-with-the-chemical-plant-long-gone-why-is-the-company-still-alive-and-what-about-all-that-mercury-pollution/). Yet, Section 2.5.2 (p.15) of the proposal explicitly identifies that siting decisions of the treatment facility were made with consideration for sensitive environmental features and that mitigation and compensation measures were developed where avoidance was not possible.

  > "NPNS has emphasized project design and siting so that the location and configuration of the project facilities considers the above measures wherever possible so as to avoid or minimize the potential environmental effects of the project. To the extent possible, project facilities have been sited to avoid and reduce interactions with watercourses, wetlands, areas of elevated archaeological potential, and other sensitive environmental features. Where avoidance was not possible, mitigation or compensation measures have been developed as part of the EA, and will be implemented in consultation with the applicable regulatory authorities."

  It is a gross oversight that the potential disruption of mercury contamination has not been addressed in the proposal and one can conclude that, on the basis of this proposal, the potential risk of mercury disturbance that, while present, is **unknown**.
- Northern Pulp has exhibited a poor track record with their current pipe, experiencing a number of breaks and leaks in recent years. Northern Pulp's inability to effectively maintain the integrity of their equipment over time would suggest that the ability of the company to prevent environment damage from effluent pipe breaks in the future is **uncertain** at best, not in keeping with the precautionary principle, and, therefore, too risky a prospect.
- Finally, the new effluent treatment system requires burning sludge, but the proposal does not indicate additional pollution abatement equipment that will be a part of the power boiler stack to minimize environmental impacts of burning something with **unknown** characteristics. This lack of information is particularly troubling given Northern Pulp's historical problems with the power boiler pollution filtration and the limited stack testing currently required. Furthermore, while Northern Pulp has had permits for test burns of sludge in the past, those test burns offer no assurance the sludge burning with the new system would be safe since effluent processing is entirely different and the sludge will be different given that it will undergo less 'polishing'.

ii) Some of the information provided in the application is misleading.

Some of the information provided in the application is misleading, specifically with respect to the quality of effluent that will result from the new treatment facility.

- First, in the public information sessions presented by Northern Pulp in December 2017, the effluent quality promised was contingent on Northern Pulp installing an oxygen delignification system. The proposal has been revised since the plans presented in 2017, but the promise of improved effluent quality remains despite oxygen delignification not being part of this proposal. If oxygen delignification is required to achieve the predicted effluent quality as promised, why is it not included in the proposal? And, if the proposal is assessed at face value and approved based upon predicted effluent quality dependent upon oxygen delignification, but oxygen delignification is not proposed, can the facility proceed and have poorer quality effluent as a result?
- Second, Northern Pulp's promise of improved effluent quality is misleading based upon the company's own admission in internal communication. Despite publicly claiming the effluent will be better, internal documents acquired by environmental lawyer Jamie Simpson acknowledge that it will, in fact, be worse due to losing the 'polishing' time that Boat Harbour affords. (Jamie Simpson's interview with CBC Information Morning can be accessed here: https://www.cbc.ca/listen/shows/information-morning-ns/segment/15672343)
- The two points above refer to promises by Northern Pulp that effluent quality will be improved. Yet, as previously indicated, by the company's own admission, the actual characteristics of marine effluent are unknown. Therefore, it is challenging to understand how a promise of improved effluent quality can be made, if the effluent characteristics are uncertain.
- In addition, Emma Hoffman, the author of one study cited by Northern Pulp in their EA proposal has recently responded to the interpretation of their work within the EA document and have explicitly stated that Northern Pulp has misrepresented its scientific contribution, thereby raising concern about the representation of other studies included in the proposal (Pannozzo, L., Dalhousie researcher breaks silence over pulp mill's cancer-causing air emissions, *Halifax Examiner*, March 7, 2019, https://www.halifaxexaminer.ca/province-house/dalhousie-researcher-breaks-silence-over-pulp-mills-cancer-causing-air-emissions/).

iii) There is a lack of trust that, if the project is approved, Nova Scotia Environment has the capacity to monitor and enforce compliance with regulations.

- Lastly, there is a lack of trust that Nova Scotia Environment has the capacity to monitor and enforce compliance with regulations or adequately monitor the terms and conditions of this environmental assessment, should it be approved. The provincial Auditor General has identified this specific issue as a concern as recently as 2017 where his November 2017 report clearly stated that "Nova Scotia Environment is not monitoring terms and conditions attached to approved projects", (Report of the Auditor General to the Nova Scotia House of Assembly, November 1, 2017, p. 45; https://oag-ns.ca/sites/default/files/publications/FullNov2017_1.pdf). And, using history as a guide,

NSE has demonstrated numerous challenges with effectively monitoring Northern Pulp and enforcing the regulations it has imposed as highlighted below.

- Nova Scotia Environment (NSE) has the responsibility of creating and enforcing the rules for Northern Pulp's current effluent pipe, yet there have been at least three pipeline leaks in recent years (2008, 2014 and 2018). And, despite increasing efforts by the regulator to improve pipeline monitoring by the company in response to the recent pipe breaks, those efforts did not result in preventing future leaks.
- The current monitoring and enforcement model employed by Nova Scotia Environment (NSE) requires companies self-report problems and breaches. More than a decade ago, in 2008, a review of NSE by the Office of the Auditor General identified this as an area of concern and recommended that,

> "The Division should establish procedures to obtain objective evidence to validate the accuracy of monitoring reports received from approval holders". (Recommendation 3.2, https://oag-ns.ca/sites/default/files/publications/2008%20-%20Feb%20-%20Ch%2003%20-%20Environment%20and%20Labour%20-%20Env%20Mon%20and%20Compliance.pdf)

Yet, the 2017 Report to of the Auditor General to the House of Assembly (https://oag-ns.ca/sites/default/files/publications/FullNov2017_1.pdf) notes that this recommendation had not yet been addressed. As a result of failing to implement a solution per the Auditor General's decade-old recommendation, NSE has proven to have lessened awareness of certain problems and have been unable to minimize what could be preventable environmental damage. Some examples that illustrate NSE's limited objective oversight with respect to Northern Pulp include the following:

- Northern Pulp had problems with their power boiler scrubber identified to them by a consultant in 2006, but NSE did not become aware of the situation until 2008. Had NSE been relying on objective oversight, the problem could have been identified much sooner rather than obliviously allowing the company to continue operations.
- Subsequently, NSE issued an industrial approval in 2011 despite the company failing to address their air pollution problems. The Minister of the Environment stated that NSE was unaware of the ongoing air pollution issues when the 2011 Industrial Approval was issued despite evidence to the contrary provided by NSE to the environmental group Clean the Mill (CBC News, Northern Pulp air quality monitors years behind schedule, October 7, 2014, https://www.cbc.ca/news/canada/nova-scotia/northern-pulp-air-quality-monitors-years-behind-schedule-1.2789892). It was not until 2012 that NSE finally issued a directive to the company to address the problem. This example illustrates a lack of communication within NSE, further reinforces the need for objective information to be used in decision making within the Department in order to prevent damage from environmental regulation violations and further justifies the decreased public trust in NSE's ability to protect the environment.

- When the effluent pipe broke in 2014, NSE grossly underestimated the volume of effluent lost at be 4 to 5 million liters ((CBC News, Northern Pulp charged with releasing effluent into fish habitat, October 14, 2015, https://www.cbc.ca/news/canada/nova-scotia/northern-pulp-spill-charge-1.3270154). However, the actual volume released turned out to be 47 million liters which was only revealed in court proceedings after a federal investigation (Withers, P., Northern Pulp fined $225K for 'toxic' effluent pipe leak, CBC News, March 23, 2016, https://www.cbc.ca/news/canada/nova-scotia/northern-pulp-mill-effluent-leak-fine-1.3504203). NSE has no way to independently monitor the current pipe or that proposed in this EA application not does it have the ability to validate the information reported by the company. As a result, NSE must rely on the face value of information provided by the company, a situation that has proved problematic in the past.
- Despite Northern Pulp's 2015 Industrial Approval requiring the company 'operate and maintain real time flow monitoring equipment ... designed to immediately notify the approval holder in the event of a total loss of flow or a reduction of flow below normal operating conditions', it was a member of the public that identified and reported the most recent pipe leak in October 2018. (Brimicombe, H., Northern Pulp line springs another leak, *The Advocate*, http://pictouadvocate.com/2018/10/24/northern-pulp-line-springs-another-leak/).

- Where Northern Pulp's information has proved inaccurate in the case of the 2014 pipe break, was missing in the case of the malfunctioning power boiler scrubber between 2006 through 2008, and the public needed to report the pipe break case of 2018, it seems unrealistic to think that NSE has the capacity to effectively monitor a new pipe and proactively limit environmental risks.
- Over the years, NSE has issued multiple directives to Northern Pulp to correct air emissions violations. Yet, these directives were ineffective at generating an immediate solution. Instead, Northern Pulp was given excessive timelines (often years) to correct problems. If a problem occurs with the proposed pipe or at the proposed new on-site treatment facility, problems need to be able to be identified and addressed immediately not with the excessive timelines we have become accustomed under the current monitoring and enforcement model. There is no amount of time that would be acceptable to fix problems that risk damaging the Town of Pictou's watershed or the commercial fishery.

In summary, I remain wholeheartedly opposed to Northern Pulp's effluent treatment proposal. Several aspects of the proposal are inconsistent with the principles of sustainable development that are supposed to be protected with the *Environment Act.* The information provided in the proposal documentation is misleading. And, finally, there is a lack of trust that, if approved, Nova Scotia Environment has the capacity to monitor and enforce compliance with regulations.

Sincerely,

To: The Honourable Margaret Miller, Minister of Environment

Re: Response to Northern Pulp's Environmental Assessment

Dear Minister Miller,

I am writing to submit comments on Northern Pulp's Proposed Replacement Effluent Treatment Facility Project.

I am retired from the Canadian Forces having done a tour to Camp Mirage and another to Afghanistan returned home to Pictou While there I was exposed to burning of toxic garbage, and the stench from a poo pond. In the summer of 2014, there were many days that we couldn't see the children playing in the park across the street due to the toxic smog that was hanging over the Town of Pictou. I was appalled that the Province of NS was allowing the same toxicity to happen in Nova Scotia that had happened in Afghanistan. It was clear at that time that Northern Pulp didn't care about those being exposed to the toxins, Pictou County or the Province and it took public pressure and our taxpayer money to force Northern Pulp to fix the problem.

At that time, I was oblivious of Boat Harbour and the environmental racist disaster that was in my backyard. Late in 2017 I read a book by Joan Baxter that clearly explained the problems with the pulp mill across Pictou Harbour. I was once again appalled that in Canada a company could try to block the release of this book. I was quickly losing respect for the owners of Northern Pulp. When I learned that my Provincial Government signed agreements stating that we are responsible for the effluent, in fact the Province owns the responsibility for the effluent and Boat Harbour. I asked myself how can the Province, the Department of Environment be involved in any decision for a proposed replacement to the effluent treatment plant, when in fact it will be their plant, paid for by taxpayer dollars? This is a blatant conflict of interest.

I next asked myself how the Nova Scotia Department of Environment could decide on effluent going into the Northumberland Strait when it does not just affect Nova Scotia, it affects PEI and New Brunswick.

So, you are in a conflict of interest making a decision for 3 provinces, sounds like Afghanistan to me but this is Nova Scotia, this is Canada. I asked myself how this can be happening.

Then I looked at the proposed plan to dispose of the effluent, going overland, across the Pictou watershed, to Caribou Harbour. Now, Northern Pulp would have me believe that this effluent won't affect our fish, our wildlife or our beaches but I find that very difficult to believe. Nothing lives in Boat Harbour, even treated effluent is so hot it has a kill zone. So, I wondered to myself, if they think we are all stupid. Does the Province, do you think we are stupid enough to accept another Boat Harbour, we will be surrounded by toxic chemicals, we will be at risk of their pipes, which periodically break and spill effluent, polluting our Pictou watershed and our water.

I didn't come back from serving my country, to be exposed to toxins on all sides and I will tell you right now you might as well wipe Pictou off the map, pay off all the residents, pay off all the fishermen because we will have no future in Pictou County if you allow this pipe to flow into Caribou Harbour. This is not Afghanistan where a government can do whatever it wants to its citizens, this is a democracy. Conflicts of interest, blatant greasing of palms are illegal, as well as immoral. The Nova Scotia Department of Environment should not be making this decision, this decision should be assessed by the Federal Department of Fisheries and the Federal Government.

My understanding is that within the Act, the Minister must make their decision on factors set out in the Environment Act. You must decide if the project will cause adverse effects or significant environmental effects and if so, can they be mitigated. Well, I say:

1. Any death of fish and lobster spawn is an adverse effect and any loss will be significant to the billion-dollar lobster fishery in PEI, NS and New Brunswick and can't be reversed or mitigated. Boat Harbour proves this, you might as well pave it over it is so full of dioxins, ferons, and mercury it will be decades before it is habitable. I would not consider Boat Harbour closure, and cleanup mitigating the effects. Is this the plan for the Northumberland Strait and Caribou Harbour, and the Pictou Watershed, pollute it for 10 years and then do another cleanup costing us, the taxpayers, millions of dollars. How do you mitigate the loss of quality of life, loss of tourism and loss to the billion-dollar lobster fishery? In my opinion, you can't. And once again how can you make a decision that affects 3 provinces?
2. A spill in the Pictou watershed is an adverse effect, we don't salt in the watershed, no pollution is allowed in the watershed, once there is a spill there will be no way to repair our watershed. This is an adverse effect that has happened many times over the 50 years the pulp mill has been in existence and it is very probable that this will happen in the Pictou watershed. The First Nations have been drinking bottled water for decades, would you consider this mitigating the effects? I would not. It is unacceptable to run this pipe over the Pictou watershed and it is once again apparent that Northern Pipe does not care about the citizens of Pictou or Pictou County by considering this an acceptable plan.

In closing, I would like to state that environmentally Northern Pulp has poisoned our air, our water, and our lands in Pictou County. We suffer higher rates of unusual cancer, lung issues, etc. Tourists smell the stench and leave, affecting tourism operators and offshoot businesses. For 50 years these effects have not been mitigated, they are significant environmentally, personal health, and enjoyment of Pictou and Pictou County. It is time for the Nova Scotia Department of Environment to take to task Northern Pulp

and not accept a pipe going into any waters, overland or otherwise. A closed loop system is the only solution to Northern Pipe remaining in Pictou County. I hope you are not another member of the old boys club that failed to look out for people who elect them, and failed to protect sustainable and viable local industries such as in-shore fishing and tourism while supporting unsustainable and polluting industries such as pulp and paper which harms the environment, and treats this province like we are a third world country. This is not Afghanistan, I exhort you to stand firm and move forward environmentally and not backward, there can be no pipe in Northumberland Strait/Caribou Harbour and Boat Harbour must close.

Yours truly,

Signed in agreement,

Postscript:

, have contacted the Department of Environment by phone, many times and left messages never to have any calls returned. I look forward to your reply to this letter.

Subject: In support of Northern Pulp"s EA application
Date: March 9, 2019 11:07:00 AM

I am writing in support of the Environmental Assessment application submitted by Northern Pulp for its new treatment facility.

A lot has been said about Northern Pulp and its impact on the local community. I stand in agreement with many, including Unifor, that Boat Harbour must close and be cleaned up to respect Pictou Landing First Nations people and their land. I also know there are many positives about having 300 good-paying jobs in Pictou, supporting thousands more across Nova Scotia, particularly in rural communities.

The Nova Scotia Environment Act is an essential piece of legislation designed to protect our shared environment and guide our economic development. The Act rightly spells out its purpose through a set of principles for sustainable development that should guide its application, including:

------> The linkage between economic and environmental issues, recognizing that long-term economic prosperity depends upon sound environmental management and that effective environmental protection depends on a strong economy.

In this situation, science should determine the best path forward. Nova Scotia, along with the rest of Canada, has among the highest global standards for environmental stewardship in the forestry sector.

The job of government and every person we elect to represent us in government is to find the best way forward when there are many competing and sometimes opposing interests. Communities across Canada manage to find a fair balance where good mill jobs coexist with a prosperous fishing industry and thriving communities.

We can and must find this balance for Pictou. There is a lot at stake: jobs, the environment, and respect for First Nations. We can and must find a solution that supports all three.

Thank you.

RE: Northern Pulp's Replacement Effluent Treatment Facility Project

Dear Minister Miller,

I have been active working with a number of groups over the past few years on the critical environmental problems surrounding offshore drilling including its dire effect on marine mammals, the risks to our seafood and tourism industries, and above all the industry-captive nature of our offshore regulatory regime, notably the CNSOPB. What does this have to do with Northern Pulp's proposed Effluent Treatment Facility? Everything. The problems and effects are the same.

The way we treat our oceans, plastic dumping, chemical dumping, our continued reliance on fossil fuels in the face of spiraling temperatures and the coming climate change cataclysm, all these things are fundamentally related to the Northern Pulp proposal.

I have read their submission in detail and find their treatment of facts both cavalier and unrealistic.

For example, their proposed Activated Sludge Treatment system can't be fool proof as they argue. Considering the mill's appalling history of dissembling and extorting financial support from successive provincial governments, their track record is as polluted as the effluent they propose to spew into the Northumberland Strait. Note the blurred lines between the regulated and the regulator including retired politicians now working on the corporate side, not to mention their proposed "new" system's reliance on a power boiler with a dismal emissions record.

Despite the best intentions of your Staff, to have a provincial EA executed by a government in the case of the Pictou mill so beholden and prey to political influence is totally unacceptable.

I do not envy your responsibility to make a decision in this case, and urge you to contribute to finding a real solution to the problem, not some rushed and cursory proposal from a dilatory proponent with zero skin in Nova Scotian's long term game. In my opinion, we should show Paper Excellence the door and start encouraging the re-design of our forestry industry per the Lahey Report, and adopt a Green Jobs approach to re-tooling Nova Scotia's paper manufacturing industry. Trying to retrofit a decrepit 50 year-old mill is clearly a poor choice for Nova Scotia's future.

Thank you for the opportunity to express my opinions.

---

Hello ,
Further to my email yesterday, I am submitting our final document for our EA response. Please see attached document entitled, "Working Group Submission - Marine Perspective". You should now have in your possession the following documents from the Fishermen's Working Group.

1. Technical Review Submitted by Shared Valued Solutions on behalf of Fishermen's Working Group
2. Fisheries Industry Submission on NPNS ED
3. Appendix A. Dr. Andrea Battison, Animal Health Perspective with a Focus on Crustaceans
4. Appendix B, Dr. Battison's publications List
5. Appendix C, FOIPOP Excerpts
6. Working Group Submission - Marine Perspective

If you could acknowledge receipt of the above listed documents, it would be greatly appreciated.

Sincerely,

On behalf of the Fishermen's Working Group for the NPEA

March 8th, 2019

Dear Hon. Minister Miller:

Please find below concerns expressed by the Gulf Nova Scotia Fleet Planning Board, the PEI Fishermen's Association, the Maritime Fishermen's Union and Pictou Landing First Nation. The four groups together represent approximately 3000 commercial fishing licenses including 215 communal commercial licenses held by 18 Aboriginal organizations

There are numerous commercially important species in the Northumberland Strait including but not limited to lobster, rock crab, Atlantic halibut, tuna, mackerel, herring and American eel. The Strait is considered somewhat of a closed system with a delicately balanced ecosystem based on a complex food web. The fishing associations are in a perfect position to examine Northern Pulp Nova Scotia's (NPNS) EA Registration Documents from the marine perspective because of their extensive knowledge of each species and their interaction with each other. This knowledge comes directly from harvester experience coupled with the organization's involvement in stock assessments, collaborative research with DFO, and numerous advisory groups.

Armed with this knowledge the fishing organizations are extremely concerned with the lack of solid evidence in NPNS's proposal that this effluent will not alter the ecosystem in the Northumberland Strait. An alteration of the ecosystem could be due to a change in water chemistry, sedimentation, or negative health effects on marine life.

The organizations feel strongly that this environmental assessment, submitted by Northern Pulp, is insufficient and it should have a more rigorous assessment. This needs to include field work and research from an ecosystem perspective with consideration given to the climate change currently being documented in the Gulf of St. Lawrence.

We are asking you to reject Northern Pulp's proposal as presented and require NPNS to file a thorough and rigorous Environmental Assessment Report.

It is important to point out that a request for a more rigorous federal assessment does not set a precedent for changes to other pulp mill treatment plants to go through a federal assessment. The current pulp and paper effluent regulations were developed in 1992 and are currently under review so this project is a unique case while regulations are being updated.

Background information:

The mean water flow in the Northumberland Strait is west to east and the residence time is weeks to months but this varies with seasons, storms, etc. (AMEC Earth & Environment 2007). There are also 2 gyres (figures 1 and 2) located at each end of the Northumberland Strait (Fisheries and Oceans Canada 2005) affecting the residence time. These gyres have the

capability to retain and redistribute particles, being larvae or toxins (AMEC Earth & Environment 2007). These are important to understand when considering different life stages of a species because it corresponds directly with larval drift and settlement.

It is noted in the American Lobster, *Homarus americanus*, stock status in the southern Gulf of St. Lawrence: LFA 23, 24, 25, 26a and 26b report (DFO 2013) that recent models show that the Northumberland Strait is basically a secluded system based on larval recruitment compared to the rest of the southern Gulf of St. Lawrence.

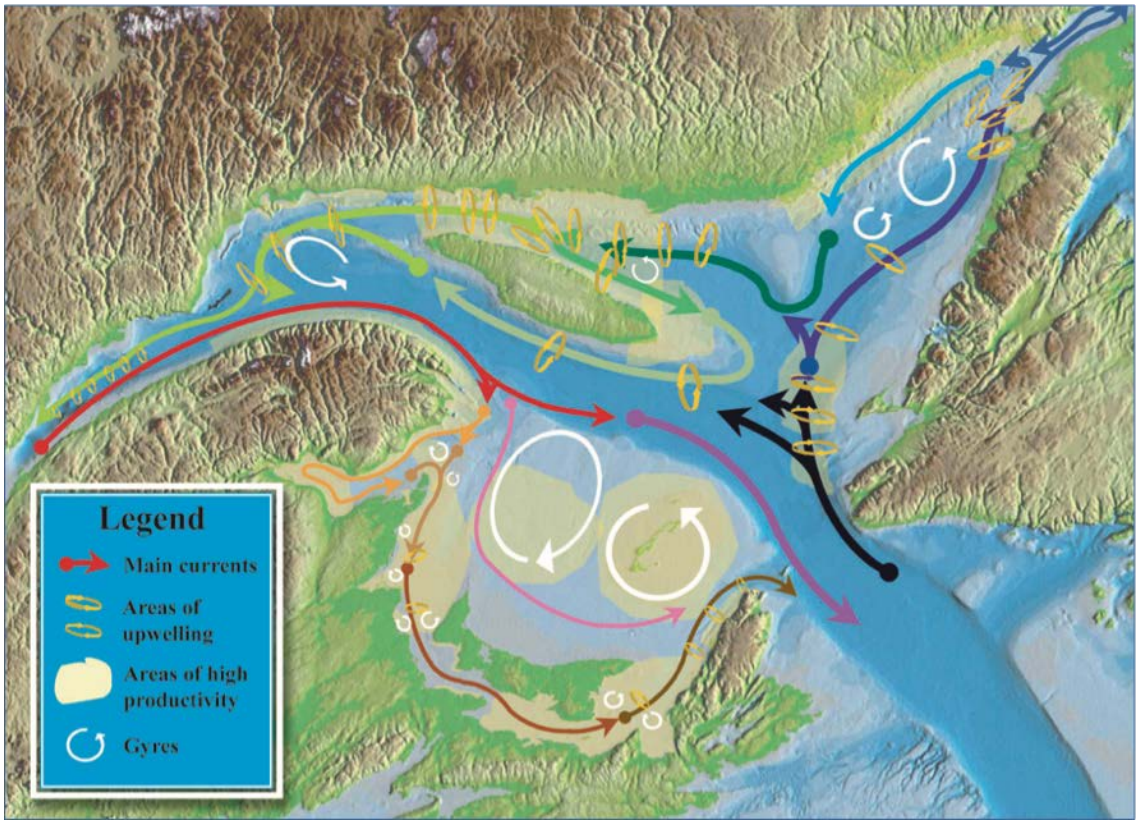

Figure 1: Currents, gyres, upwelling and areas of high productivity in the Gulf of St. Lawerence (DFO 2005).

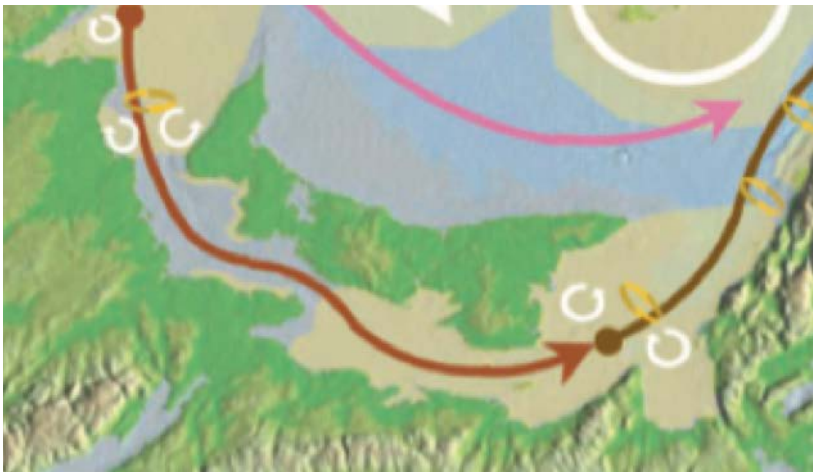

Figure 2: Section of the map from figure 5 zoomed in on the Northumberland Strait.

To give this some context, we can look at lobster larval transport in the Gulf. Based on the previous description above one can assume that anything entering the Northumberland Strait will drift toward the east, up along the Western side of Cape Breton to the Cabot Strait, and out of the Gulf, but the description leaves out the timeline of this taking place. In 2010 Joël Chassé and Robert J. Miller published “Lobster larval transport in the Southern Gulf of St. Lawrence”.

They broke down the Southern gulf to 25 larval source-sink areas (Figure 3) to look at the distribution between the time the eggs are released to the time the larvae settle. When the eggs are released they are reliant on the current for transport and only have the capability to swim to the bottom and seek out suitable habitat at stage 4 which occurs approximately 3-12 weeks after release from the abdomen. During the 3- 12 weeks the prior to settlement the larvae’s destination is a result of the direction of the current. Chassé and Miller (2010) showed that the larvae released in Pictou (area 21) actually seeds areas 23, 24, 22, 20, 18 and 19 (Figure 3). Seeding in areas 18 and 19 are to a lesser degree but still shows a distribution from east to west, exemplifying the weak current present in the Northumberland Strait. These models were run for the larval and post-larval season, June 1st to September 30th, over a 10-year period. This shows lobster larvae are retained in the Northumberland Strait for up to 120 days while a product of the current and some actually end up west of where they were released rather than east; completely contradicting the description our harvester working group is being given by Northern Pulp and their consultants. This model showed that particular circumstances result in east to west currents lasting days to weeks (Hanson and Comeau 2017).

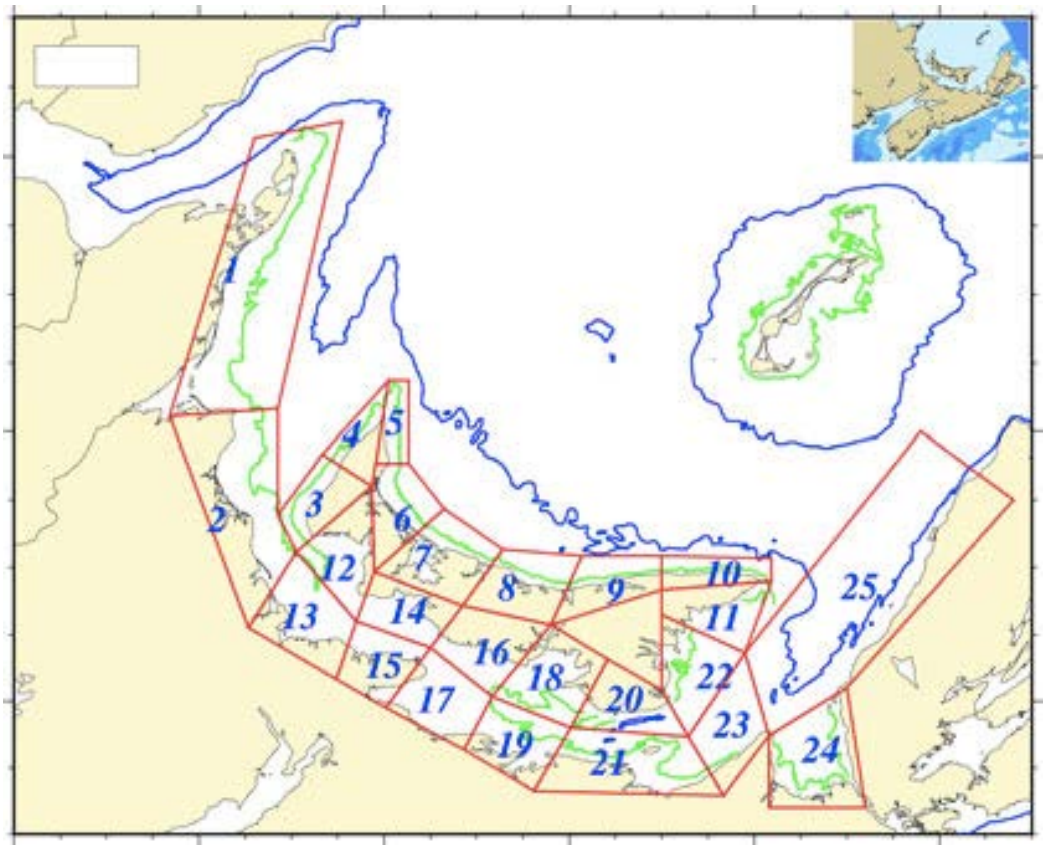

Figure 3: The 25 larval source-sink areas set up by Chassé and Miller, 2010 to analyze larval drift in the Southern Gulf of St. Lawrence.

This also shows the relationship that exists between the provinces in relation to the lobster fishery. Abundance in one area is not a product of the adults in the same area, but rather the adults in other areas and the currents that move the larvae through the Northumberland Strait and the Gulf of St. Lawrence.

Figure 4 showed a full year averaged currents in the Gulf of St. Lawrence and is represented by arrows, the darker and longer the arrows the stronger the current. It is apparent that the movement in the Northumberland Strait is greatly reduced compared to other areas within the Gulf of St. Lawrence further emphasizing the lack of circulation in the Northumberland Strait.

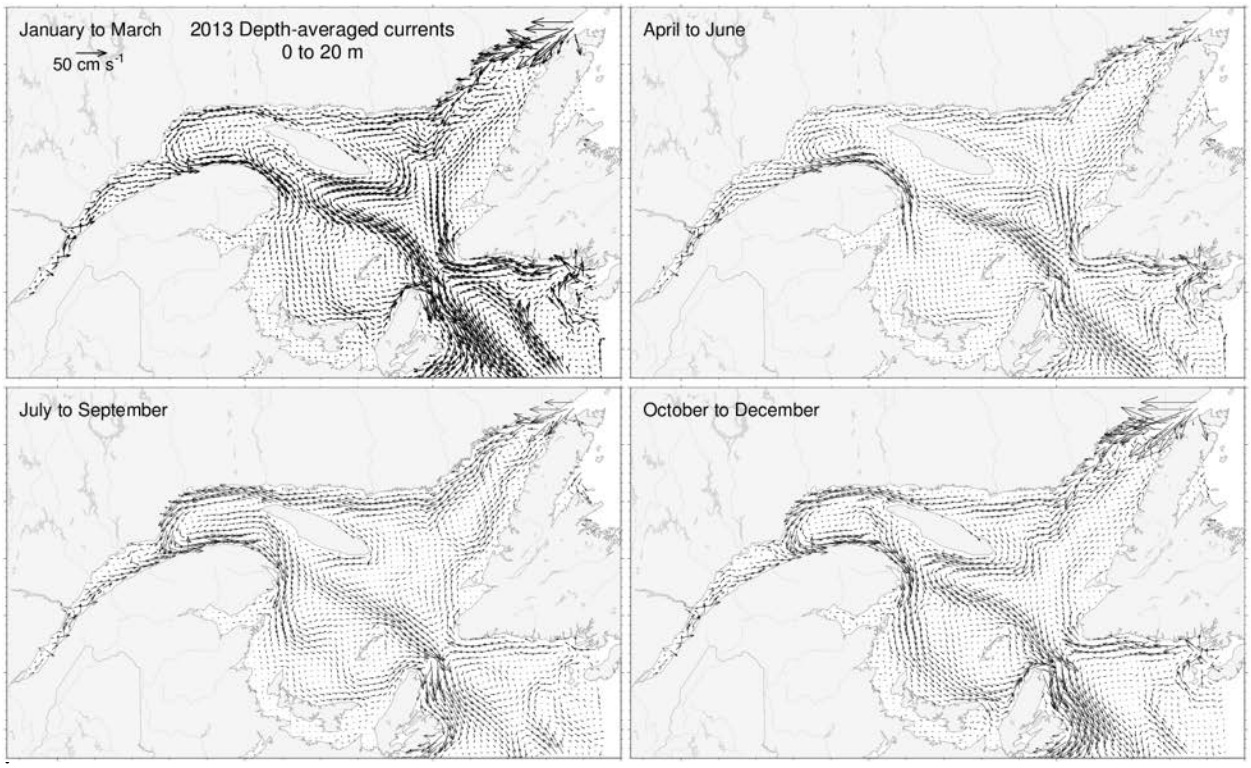

Figure 4: Depth-averaged currents from 0 to 20 m for each three-month period of 2013. (Galbraith et al. 2013)

The Gulf of St. Lawrence has been identified as an area of rapid coastal deoxygenation by Claret, M. et. al (2018). Their analysis shows increased surface water temperature, increased salinity and decreased oxygen saturation. Changes to any of these variables in isolation can cause stress on important commercial species, changes to all three has the potential for synergistic effects and should not be overlooked. The addition of hot, fresh water to the Northumberland Strait for an extended period should not be so easily passed by in this environmental assessment.

Specific Concerns from the Fishing Industry with Northern Pulp's EA Registration Document:

Issue 1: "The description of existing conditions for the harbour physical environment, water quality, and sediment quality in the Northumberland Strait, Caribou Harbour, and Pictou Harbour is based on the results of previous research and existing scientific literature and environmental assessments; no field work was conducted as part of this EA Registration." Pg. 337

Recommendation 1: A project of this magnitude warrants sufficient field work to be completed. The fact that there was NO field work adds to the gap in knowledge on this topic. Further studies should be carried out to confirm harbour physical environment, current water quality and sediment quality as a baseline for the future.

Issue 2: "Average sea surface temperature in May to December in the Northumberland Strait (1986-2012) are shown in table" (Pg. 338). The discussion around sea surface temperature draws attention to the changing ocean temperatures as a result of climate change. The Gulf of St. Lawrence has been identified as an area of rapid coastal deoxygenation by Claret, M. et. al (2018). Their analysis shows increased surface water temperature, increased salinity and decreased oxygen saturation. Changes to any of these variables in isolation can cause stress on important commercial species, changes to all three has the potential for synergistic effects and should not be overlooked. The addition of hot, fresh water to the Northumberland Strait for an extended period should not be so easily passed by in this environmental assessment.

Recommendation 2a: This data is not up to date but it is available. Care should have been taken to include up to date information. This represents a gap in scientific data.

Recommendation 2b: Fisheries in the Northumberland Strait take place throughout the entire water column. Surface, mid-water and bottom water therefore bottom water analysis is required. This is a gap in scientific data that is essential to understanding the changes that will take place going forward.

Issue 3: "This section provides an overview of water quality sampling in Pictou Harbour in 1990, 1995 and 1998 (Dalziel et al. 1993; JWEL 1996; ENSR 1999). Pictou Harbour was used as a proxy for Caribou Harbour with respect to water quality, in the absence of available water quality data for Caribou Harbour.**"** (Pg. 343).

As laid out in the opening sections of this document, proper water quality is extremely important to every species inhabiting the Northumberland Strait. Parameters have shifted over the years due to numerous stressors on the ocean, the Northumberland Strait is not an exception to this change.

Recommendation 3: Relying on data that is 30 years old is unacceptable considering the simplicity of completing these tests. This project focuses on releasing effluent into a highly productive section of the marine environment and the care should have been taken to collect all appropriate data.

Issue 4: "The main commercial, recreational and aboriginal fisheries are for lobster, sea scallop, herring and rock crab among other lesser species fished" (Pg. 356).
"Commercially important species with potential to occur in the Marine LAA include rock crab, lobster, sea scallop, herring, mackerel, and tuna" (Pg. 366).

Yes, these are some of the commercial, recreational and aboriginal fisheries that take place in the Northumberland Strait, but Northern Pulp failed to mention: mackerel, bluefin tuna, Atlantic halibut, soft shell crab, American eel, gaspereau, and silver sides.

In terms of those with potential to occur in the Marine LAA, any of these species listed have the potential to occur in the LAA, it is not restricted to rock crab, lobster, sea scallop, herring, mackerel and tuna.

A full and complete environmental assessment would take in to consideration every species fished commercially in the area to look at sensitivities of those fish to changes in water quality and negative health effects of contaminants. In this environmental assessment all species fished are not even listed, and none are researched to the extent they should be. A few examples of species missed and important information about them are below.

Atlantic Halibut are known to frequent the area and it seems that this is an area of interest during the summer/fall feeding period for them (personal communication with Dr. Arnault LeBris, 2019). Industry has played a large part in collecting data in collaboration with academia. Together we've pinpointed spawning areas through tagging studies and this is also how we know they are directly in the vicinity of the proposed pipe. This tagging study generated tracks or movements of each fish tagged. Figure 5 shows one halibut's approximate location in late June of 2015, which is directly overlapping the location of the outfall. Their normal temperature range in the summer and fall is 1°C and 15°C (Murphy, et al. 2017).

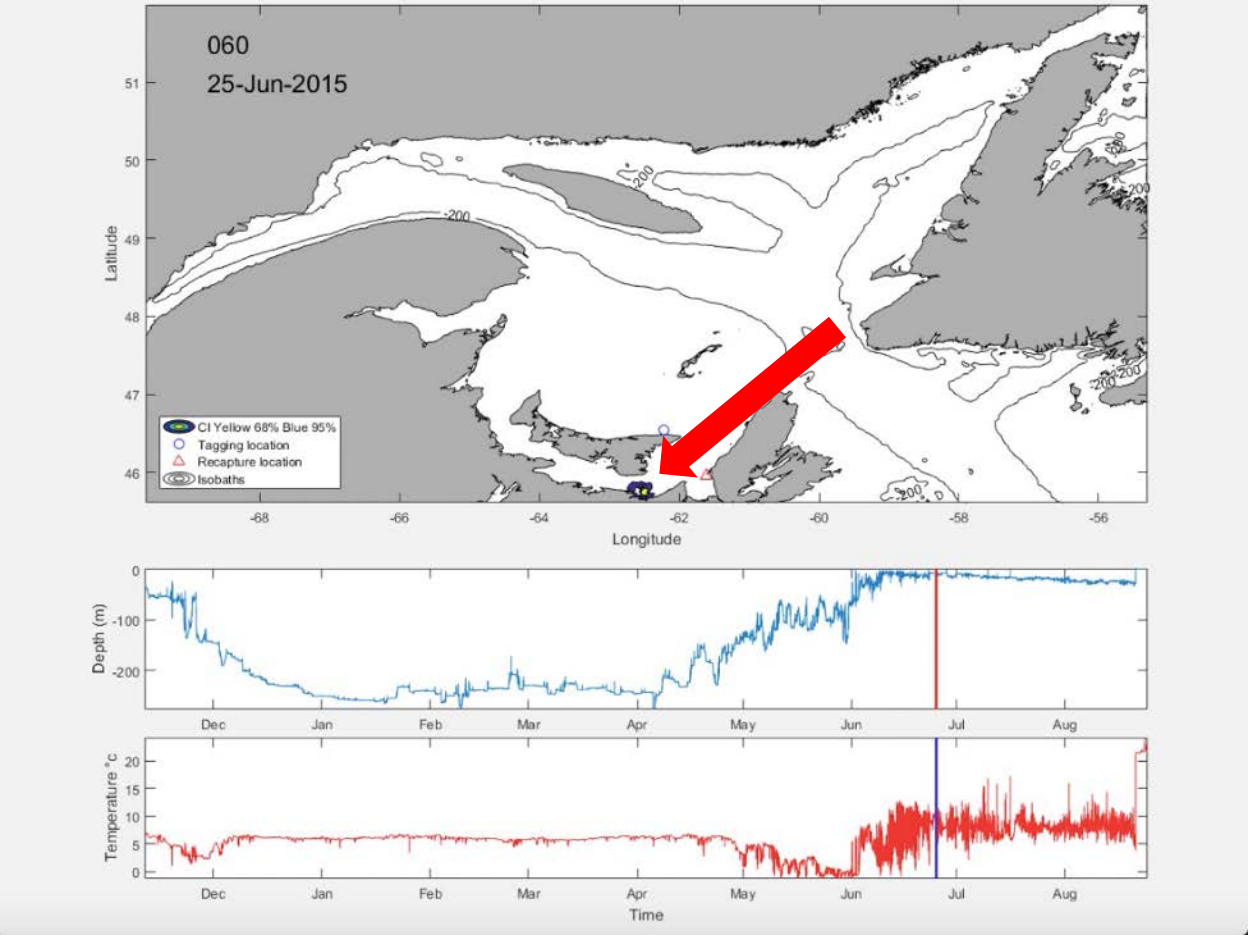

Figure 5: Location of a tagged Atlantic Halibut in late June 2015. (Arnault LeBris, Personal communication).

Recommendation 4: A complete list of species fished should have been composed with research on their tolerance ranges, sensitivities and how different contaminants in the effluent could negatively affect that species. Each species has a different mechanism for expelling toxins from their body so comparing one species to another does not work in the majority of cases.

Issue 5: Herring is caught along the shoreline of New Brunswick and Nova Scotia in the Northumberland Strait, including the Pictou area (Figure 8.12-6). There may be overlap with herring fishing and the location of the marine outfall. Concern has also been raised about the effects of the marine effluent pipeline on herring spawning as well as juvenile lobster (PEI Standing Committee on Agriculture and Fisheries 2018); however, the main fisheries in the LAA are for scallop and rock crab. Nevertheless, herring stocks are currently of concern to DFO, and attempts are being made to manage this fishery to avoid becoming at risk in the area (PEI Standing Committee on Agriculture and Fisheries 2018). Herring spawn between August and October in the southern Gulf of St. Lawrence and DFO has identified fall spawning grounds for herring in the eastern Northumberland Strait (DFO 2018) (Figure 8.12-7). (Pgs. 366-367)

This portion of the EA states that concern has been raised about the effects of the effluent on herring spawn, **however, the main fisheries in the LAA are for scallop and rock crab**. The DFO are making attempts to manage this fishery to rebuild the stock. There is NO mention of what Northern Pulp is doing

to mitigate the risk to herring spawn. Northern Pulp did not do any field or lab work on this possible interaction. This is another gap in data.

On February 20th and 21st, the Gulf small pelagic advisory met in Moncton. This advisory consists of DFO management and science, industry representatives and First Nation Communities. The advisory reviewed the current stock assessment, discussed landings and reviewed the draft of the rebuilding plan. In the management issues of the rebuilding plan the DFO state:

"Climate change and other human impacts on the ecosystem: the physical and biological shifts climate change brings, along with more direct human impacts … are modifying marine ecosystems in many ways, which often cannot be effectively monitored and quantified. Since herring are spawning in shallow coastal areas, these populations may be impacted by these changes" (Figure 6).

This clearly shows concern from the DFO regarding possible issues involved in rebuilding this stock.

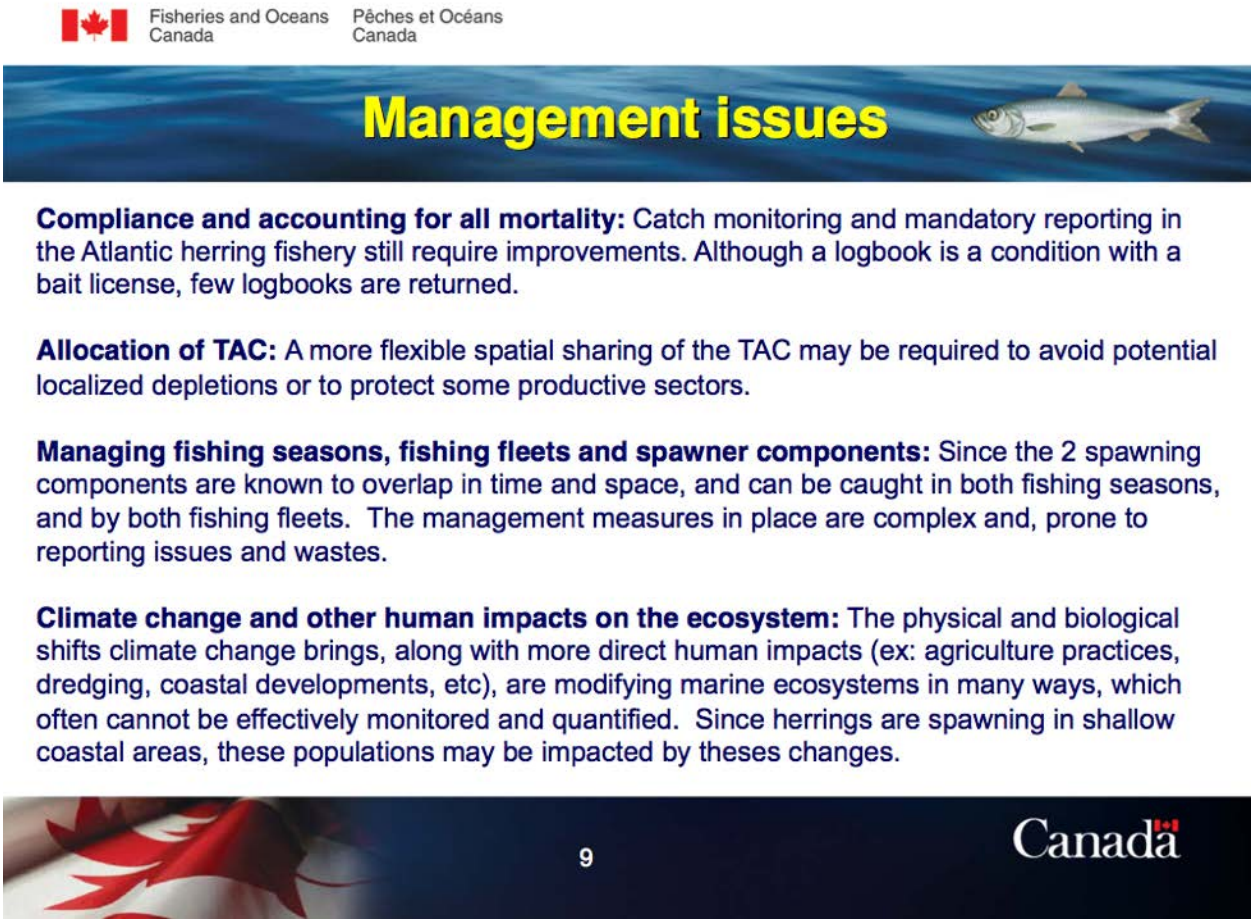

Figure 6: information on management issues from DFO's Herring Rebuilding Plan draft presented at the Small Pelagics Advisory meeting.

Recommendation 5: Proper research needs to be completed to understand possible sub-lethal effects of the effluent on herring spawn. Currently, the fall spawning stock is in the critical zone and the spring spawning stock is in the cautious zone (DFO, 2018) and a rebuilding plan is being developed to ensure the regrowth of the stock. The need for more research is obvious to assist in the rebuilding plan.

Issue 6: "Mackerel is also caught along the coast near the LAA, although most fishing occurs in the central and western portions of the Northumberland Strait (Figure 8.12-8)" (pg. 367).

This is the only comment about mackerel in the environmental assessment and it shows a lack of robust analysis. There is only a mention of fishing, no mention of life stages or their occurrence in the LAA. We know that the only spawning area in Canada is the Southern Gulf of St. Lawrence and that the egg survey has been slowly increasing since 2012 (DFO, 2017). We also know, based on those egg surveys that mackerel eggs are present in the East end of the Northumberland Strait (Figure 7).

Currently, this stock is in the critical zone but changes to management have allowed for a small increase in the last few years. For the past two years the DFO, industry and First Nations have been working together on a rebuilding plan.

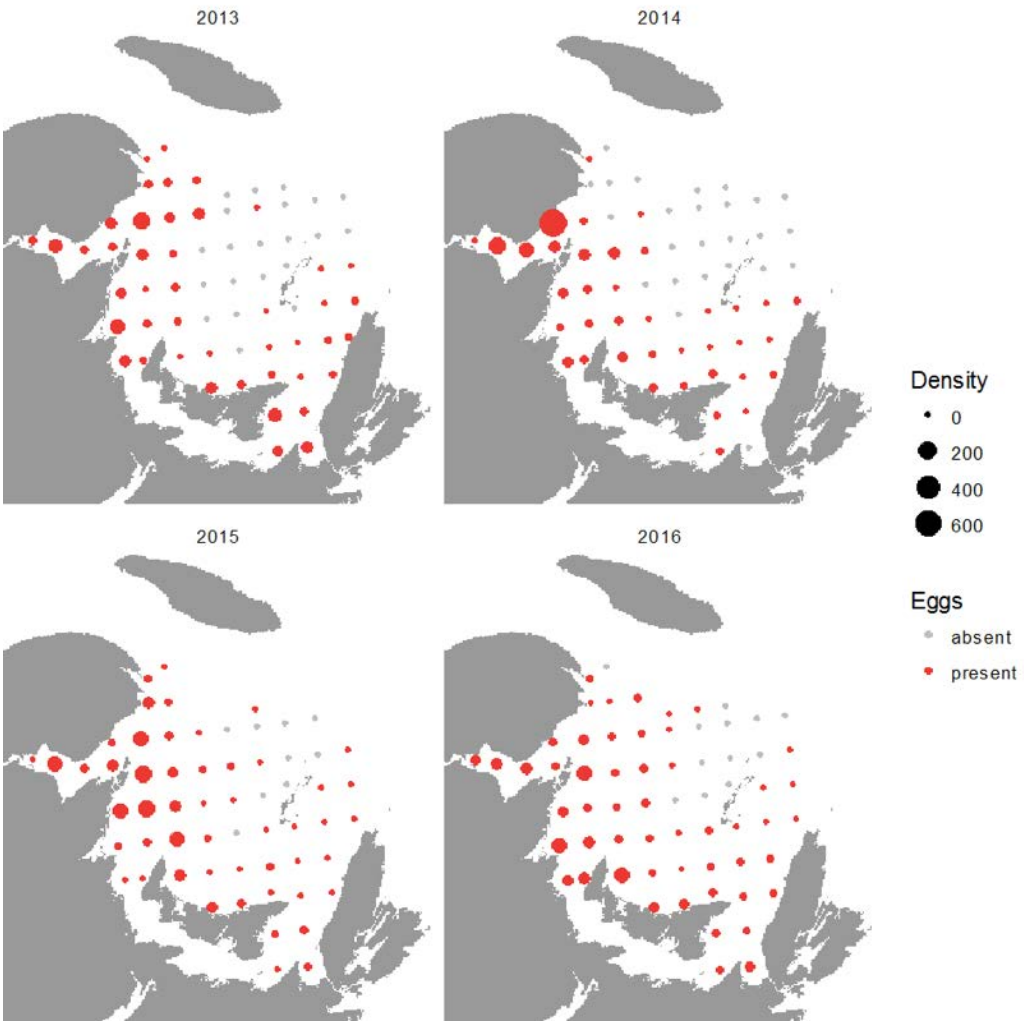

Figure 7:Distribution of mackerel egg (stages 1 and 5) densities (n/m2) measured in surveys in the southern Gulf of St. Lawrence from 2013 to 2016 (DFO, 2017)

Recommendation 6: Proper research needs to be completed to understand possible sub-lethal effects of the effluent on mackerel eggs. Currently, the stock is in the critical zone (DFO, 2017) and a rebuilding plan is being developed to ensure the regrowth of the stock. The need for more research is required to assist in the rebuilding plan and ensure all eco-system aspects are understood to give the stock biomass a chance to rebuild. This is clearly a gap in the environmental assessment data provided by Northern Pulp.

Issue 7: White Hake "This species was determined to have a high probability of being caught during DFO
research vessel trawl surveys in the eastern section of the Northumberland Strait, including the LAA (Rondeau et al. 2016)" (Pg. 381)

It is also noted on the same page, "The main reason for the decline of this species was overfishing in the late 1980s and early 1990s (COSEWIC 2013)."

This species may not currently be listed under SARA, but the DFO is currently undergoing consultation with the public regarding listing the Southern Gulf of St. Lawrence population under SARA as

endangered (Figure 8). Comment period ends on May 6th for this consultation. There is ample concern that is this species is listed and is known to be caught in the LAA what are the next steps?

White Hake stick to temperatures of 4°C to 10°C. The population normally migrates inshore in summer, and then to deeper waters during winter (DFO 2019).

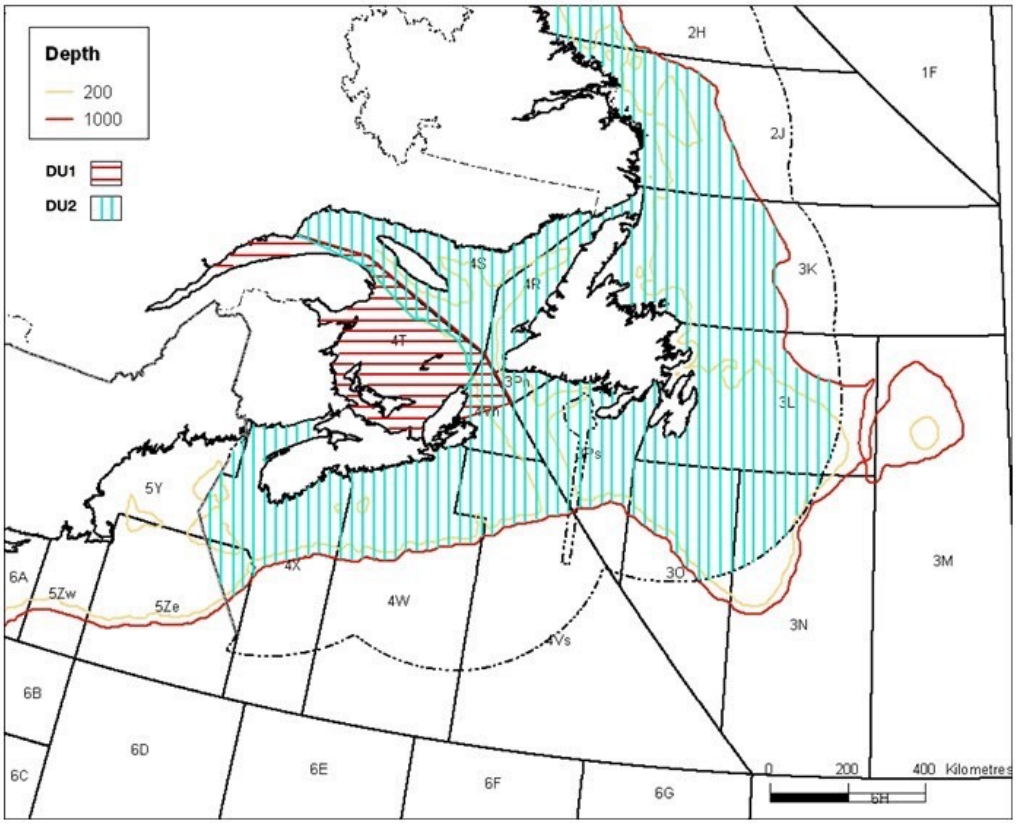

Figure 8: Differentiation between the two designated stocks of white hake, red horizontal lines show distribution of the Southern population (DFO. 2019)

Recommendation 7: The moment there is a SARA listed species in question in an environmental assessment it is supposed to trigger a federal assessment. The recommendation in this case is that Northern Pulp respect this process and request a federal assessment due to the fact that the federal government is currently seeking consultation on listing white hake as endangered under SARA. There is an enormous amount of time and energy spent on trying to rebuild stocks such as this one. Although Northern Pulp consultants laid the blame on the fisheries for the decline the truth is it was only a portion of the problem and fishing effort has nothing to do with the rebuilding struggles as DFO explains here:

"The main threat to White Hake in the sGSL is from an increase in natural mortality. Predation by Grey Seals is considered to be a major cause of this natural mortality. Over the past 3 generations (27 years), adult abundance declined by 91%. Levels of fishing removals that were sustainable in the 1970s and early 1980s became unsustainable when non-fishing

mortality increased in the late 1980s. No directed fishing for White Hake has been allowed in the sGSL since 1995."

This species is naturally struggling to rebuild and no work was done to determine how the effluent will affect the already stressed species.

Issue 8: Atlantic Sturgeon – "Table 8.12-6: Marine Fish Species at Risk and Species of Conservation Concern with Potential to Occur in the LAA." This table lists American eel, American plaice, Atlantic bluefin tuna, Atlantic cod, Atlantic salmon, Lumpfish, Porbeagle, Spiny dogfish, Striped bass, and White hake but it does NOT list Atlantic Sturgeon.

There are 2 species of Atlantic Sturgeon in Canada and both are listed as threatened by COSEWIC. There was an Atlantic Sturgeon caught off Pictou Island in 2018 as bycatch (personal communication, fall 2018). It was returned healthy and swimming to the ocean.

Recommendation 8: This is another instance of a lack of comprehensive research done by Northern Pulp on a very lucrative and productive marine eco-system. More research required.

Issue 9: Potential Environmental Effect "Routine effluent discharge from the effluent outfall diffuser will cause a project-related change in water quality. The treated effluent will contain the following water quality parameters of concern: absorbable organic halides (AOX), total nitrogen (TN), total phosphorus (TP), colour, biochemical oxygen demand (BOD), total suspended solids (TSS), dissolved oxygen (DO), pH, and water temperature. Potential effects could result from:

- an increase in temperature, nutrients (nitrogen and phosphorus), and/or TSS;
- a change in colour, chemical and BOD, DO, and/or pH; and/or
- a reduction in salinity from the discharge of relatively freshwater effluent into the Northumberland Strait.

The discharge of effluent containing elevated levels of TSS could also cause a change in sediment quality near the diffuser due to settlement of suspended sediment," (Pg. 347)

This paragraph amplifies industry concern. As mentioned above, with the few species discussed, a change to any of these parameters can have detrimental effects on the fishery and this paragraph states in black and white that potential effects could result from any of them.

Increased TSS coincides with a change to the habitat and possible suffocation of benthic species.

Recommendation 9: Time should have been dedicated to understanding each species upper and lower limits for their environment as well as upper and lower limits for toxins specific to Pulp and Paper Effluent. The Pulp and Paper Effluent Regulations only monitor a few levels and are not stringent enough. This is based on the fact that Environment and Climate Change Canada are currently reviewing the regulations to make them more stringent and include other contaminants. A review and research should be done to understand how changing water quality coupled with toxins could affect each species inhabiting the area.

Issue 10: "Modelling results indicate that there are few traces of relatively high diluted effluent after a period of 30 days" (Pg. 350)

This is part of the accumulation the industry is concerned with. This plant is not going to run for 30 days and then stop this pipe will dump effluent into the Northumberland Strait 24 hours a day, 7 days a week potentially for years to come. Those few traces will add up overtime, remaining in the Northumberland Strait.

It is also key to remember that a model is a prediction, it is not exact. A scientific model is defined by Encyclopedia Britannica as: "the generation of a physical, conceptual, or mathematical representation of a real phenomenon that is difficult to observe directly. Scientific models are used to explain and predict the behaviour of real objects or systems and are used in a variety of scientific disciplines, ranging
from physics and chemistry to ecology and the Earth sciences. Although modeling is a central component of modern science, scientific models at best are approximations of the objects and systems that they represent—they are not exact replicas."

Recommendation 10: The industry is interested in a better understanding of the long-term effects of the effluent. As stated in the early pages of this report fishing has existed for hundreds of years and with healthy oceans the stocks will continue for hundreds more. More work should have been done to look at the effluent remaining in the Northumberland Strait for the long term. This would also take into account the changing climate (increasing temperature, salinity and decreasing oxygen saturation).

Issue 11: "A significant adverse residual environmental effect on marine fish and fish habitat is one where project related activities:

- Cause a significant decline in abundance or change in distribution of a marine fish population within the Northumberland Strait such that natural recruitment may not re-establish the population to its original level within one generation"

"No field work was conducted as part of this EA registration" (Pg. 358)

One generation means very different timelines for each species. This could be 2 years for a species like mackerel, 5-7 years for a species like lobster or 12 years for an Atlantic Bluefin tuna. In any case too much damage could be done to a population during that timeline to be acceptable to the industry. If there is damage to larval lobster and it is not understood or mitigated until it reaches size at maturity there will be 5-7 year classes following that initial one that will also be negatively impacted.

Recommendation 11: Again, this is a gap in the data. More research should have been done to better understand each species with a mitigation plan in place for each with a timeline based on their generation timelines.

Issue 12: "Figure 8.12-5 presents scallop catch weights from 2010-2014 in the Northumberland Strait where there is an overlap of the route of the pipeline and at the outfall location. Since 2014, a Scallop Buffer Zone in Scallop Fishing Area (SFA) 24, discussed further in Section 8.12.2.7, prevents scallop fishing in this area, except potentially at the location of the outfall" (Pg. 366).

The above paragraph is basically the only mention of sea scallops in Northern Pulp's environmental assessment. They are a species fished directly in and around the LAA, but only get the same attention as species apparently not fished in the area (according to Northern Pulp's consultants). Sea scallops will normally grow when they are between 8°C and 18°C, ideal temperature for growth is 13.5°C. Ideal salinity is between 30 to 32 ppt but they can tolerate salinities as low as 25 ppt. Sea scallops, although a bivalve are still an animal and are prone to being stressed in environments outside of their normal ranges, in this case they get stressed between 20°C and 23°C and mortality will occur at temperatures of 23.5°C and greater. The Southern Gulf of St. Lawrence has experience mass die offs in the past. (DFO, 2011)

Temperatures will not reach background levels until 100 m from the outfall site and the proposed effluent release will be 26°C in the winter and 37°C in the summer. This is much higher then mortality causing temperatures for the sea scallop.

Figure 9 shows locations of fishing effort in 2009. Although this effort is outdated fishing takes place on scallop beds so the concentrated effort would still be around the same areas as seen in 2009. The purpose of this map is to point out that a large portion of the fishery takes place in the vicinity of the proposed outfall location and therefore there are numerous sea scallop beds in the location susceptible to increased water temperatures.

For more information on collaborative research between the fishing organizations, the DFO and academia please see Appendix A.

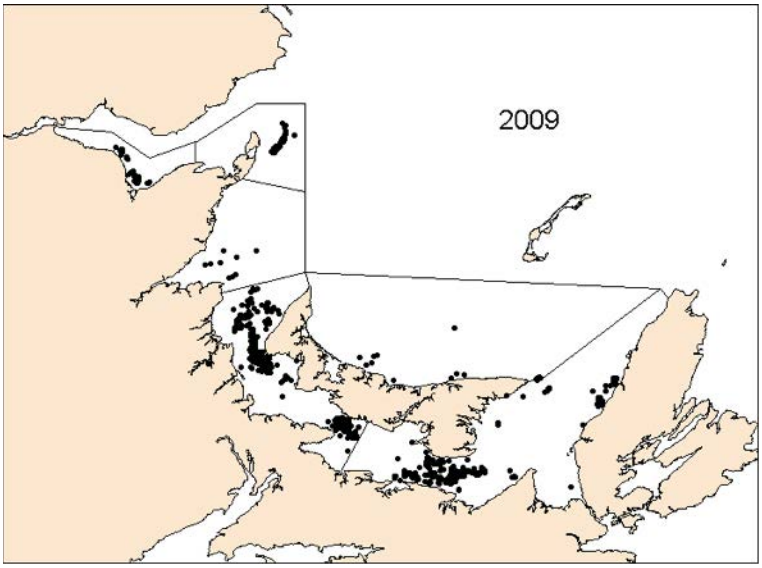

Figure 9:Map of fishing effort positions reported in the 2009 fish harvesters' logbook (DFO. 2011)

Recommendation 12: The information provided proves the susceptibility of sea scallops to temperature and that they inhabit the area near the proposed outfall location. This justifies the completion of detailed field work and trials in the area prior to the release of the proposed effluent to ensure there will be no negative effects on the sea scallops.

Issue 13: "NO field work was conducted as part of this EA registration for marine mammals, sea turtles and marine birds. In particular, this section relies substantially on the EIA registration for the PEI-NB Cable interconnection upgrade project" Pg. 395

Recommendation 13: A project of this magnitude warrants sufficient field work to be completed. The fact that there was NO field work adds to the gap in knowledge on this topic. Further studies should be carried out to confirm frequency of marine mammals in the area.

Issue 14: "NARW are not known to occur in the vicinity of the LAA and no historical observations of this SAR have been recorded in the Northumberland Strait, according to data obtained from DFO (2017) and OBIS (2018)." Pg. 400

"As noted in Sec?on 8.13.2.1, several North Atlan?c right whales were killed by vessel collisions and fishing gear entanglement in the Gulf of St. Lawrence (outside of the Northumberland Strait) during the

summer of 2017. However, this SAR is not known to occur in the Northumberland Strait and is therefore unlikely to be at increased risk of injury or mortality from vessel strikes or entanglement from the project." Pg. 420

Recommendation 14: If all documentation is reviewed it is clear that NARW have been reported in the Northumberland Strait in the past, most recently in 2015 when a female and her calf were spotted in St. George's Bay (Fig. 6).

There are currently strict management measures in place to prevent interactions between fishing and North Atlantic Right Whales. These management measures include flexibility outside of the designated dynamic zones. The management measures outside of the dynamic zone are on a case by case basis. A sighting of one whale may be handled different than a sighting of 3 whales together and different again for a sighting of a mom and calf.

Considering there is at least one reported sighting in the Northumberland Strait, it should be noted that there is an increased risk of injury or mortality from vessel strikes or entanglement from the project.

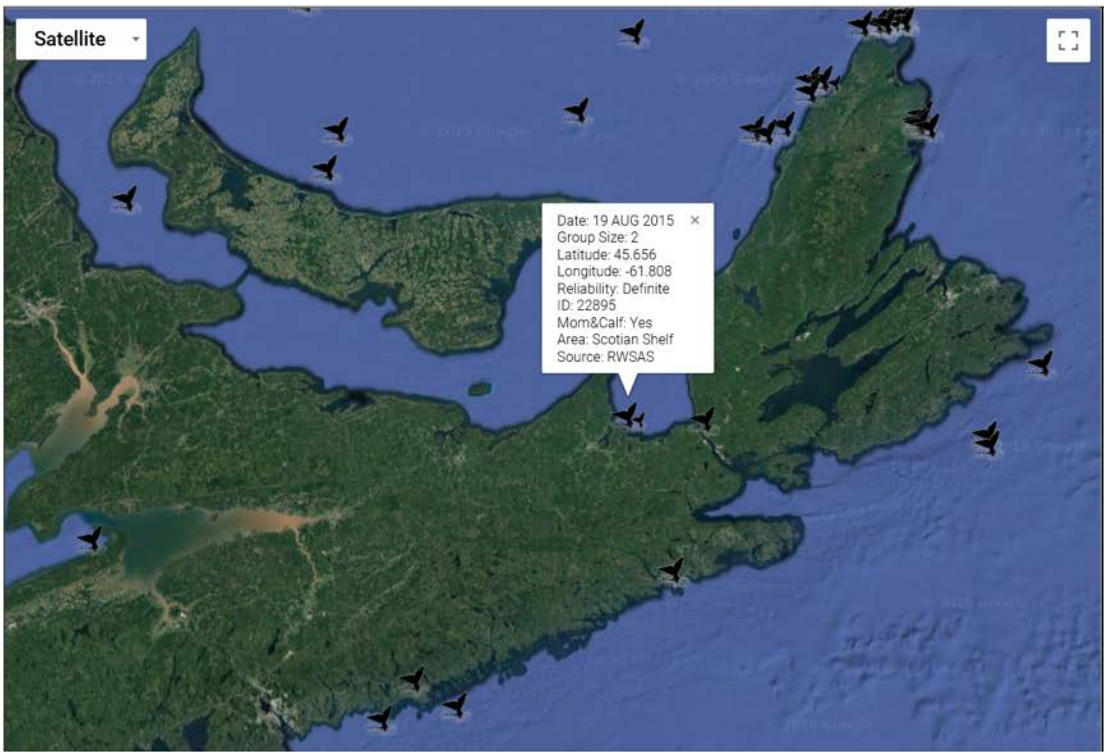

Figure 10: Sighting of North Atlantic Right Whale in the Northumberland Strait in 2015 along with calf (https://www.nefsc.noaa.gov/psb/surveys/MapperiframeWithText.html)

Issue 15: "A significant adverse residual environmental effect on the socio-economic environment is one where project-related activities directly interfere with the use of the land or water such that their intended use is no longer possible" (Pg. 431)

This is significance defined by Northern Pulp and/or it's consultants. The lobster fishing season lasts 2 months, a total of 61 days (minus Sundays as they do not fish on Sunday). This

leave a little over 50 fishing days. A loss of 5 or more of these fishing days is significant to the harvesters. This loss could be due to construction interference, negatively affected water quality driving the species off fishing grounds or sound from marine blasting driving the species away.

Recommendation 15: The definition of significant needs to be changed in this case (and others). What is defined as significant to Northern Pulp and/or their consultants is not an agreed level of significance to the harvesters in the area. If Norther Pulp would have completed proper consultation through this process the harvesters could have explained this.

Issue 16: "NPNS has attempted to engage commercial and PLFN fish harvesters to obtain fisheries data in the area of the marine outfall, but there was little interest from the fish harvesters to partcipate or provide any data (see Sec**?**on 6 Public, Regulatory and Indigenous Engagement)." (Pg. 366)

This comment is concerning to the Harvester working group because they did engage in discussion surrounding fishing grounds. It was made clear to Northern Pulp that if there was water there was fishing. Harvesters do maintain their tradition grounds, but they consistently explore other areas outside of their traditional areas. As biomasses evolve so do the traditional grounds they are found on. Lobster stocks are currently on the rise, so they are being found in areas they not have been found previously.

Recommendation 16: Each species cannot be pinpointed to specific locations within the Northumberland Strait. Again, they do have traditional habitat and areas they are commonly found, but individuals are not restricted to these areas only. The capability of each species to move throughout the Northumberland Strait must be considered and accounted for.

Issue 17: "While the majority of the commercial fishery for rock crab occurs in the central and western portions of the Northumberland Strait, there are areas in the eastern portion where rock crab is harvested, including Caribou Harbour where there is overlap with the proposed marine route of the effluent pipeline (Figure 8.12-3)." (Pg. 366)

Rock crab is another species of extreme importance in the Northumberland Strait, both for its commercial value, and it's position in the food chain. According to the DFO 2013 CSAS on *Homarus americanus* (American Lobster) which represents the most recent full CSAS, "Lobster is largely carnivorous and decapods were the principal prey (57% to 84% of prey biomass), with rock crab being the single most important component of the diet (45% to 78%). About 70% of the rock crab consumed by lobster represented fresh prey (muscle or gills attached) and the remainder consisted of old carapaces."

A decline in the rock crab biomass could also be detrimental to the lobster biomass

Recommendation 17: On numerous occasions in discussions with Northern Pulp the harvester working group recommended understanding the Northumberland Strait as an eco-system not on an individual species by species bases. This has not been accomplished in the environmental assessment submitted by Dillon Consulting on behalf of Northern Pulp.

Issue 18: "Lobster is caught throughout the central and eastern portions of the Northumberland Strait and there is overlap with the proposed route of the effluent pipeline and the location of the marine outfall (Figure 8.12-4)." (Pg. 366)

The Gulf of St. Lawrence (GSL) American lobster is the most valuable in the region, with 33,000 mt of lobster worth $445 million landed in 2016 (DFO 2016), and abundance indices still increasing

throughout the Gulf (DFO 2016, DFO 2016, DFO 2016, DFO 2016). The value of American lobster is never mentioned throughout the environmental assessment submission. The fact that the biomass is increasing is mentioned, but the reasons for the increase are not mentioned. The harvesters in the Gulf region have been working for years toward voluntary management changes to help increase the biomass. These include but are not limited to increased carapace size, returning window females (all females within a certain size range) back to the water, escape mechanisms, returning berried females, etc. Below you will see a comparison between 2012 management measures (figure 11) and 2018 management measure (figure 12) to demonstrate the efforts harvesters make to ensure a sustainable fishery.

Table 1. Key management measures in the lobster fishery in the southern Gulf of St. Lawrence that were in effect in 2012.

	Lobster Fishing Area (LFA) and subarea										
	23				24	25	26A			26B	
	23A	23B	23C	23D			26A1	26A2	26A3	North	South
Fishing season	May 1 to June 30				May 1 to June 30	Aug. 13 to Oct. 14	May 1 to June 30[1]			May 2 to June 30	May 1 to June 30

26B north/nord	82.5	s/o n/a	250	5 casiers / 5 traps	152		

Figure 12: table of the 2018 management measures presented by DFO at the Southern Gulf Advisory meeting in Moncton in December 2018.

There is a high exploitation rate in the lobster fishery leaving the fishery dependent on strong larval recruits (DFO 2013). This is the reason the harvesters protect egg bearing females and it is also partially the reason for increasing the carapace size in some regions, larger females result in more eggs in the water and the guarantee every female will spawn at least once (rather than 50%) prior to being harvested.

It should also be noted that conditions like water temperature can impact the distribution of lobster and and their catches (DFO 2013). This is extremely important to the fishers in the area of the outfall considering the temperature being released will be well above the average for the given time of year (27 degrees Celsius in the winter and 36 degrees Celsius in the summer).

Recommendation 18: In Appendix R of Northern Pulp's environmental assessment it is recommended that more research be completed on the effect of the effluent on lobster in each life stage, although this was omitted from the executive summary written for the environmental assessment. Considering the effort harvesters contribute to understanding the eco-system they rely on and the changes the harvesters are implementing, voluntarily, to ensure they maintain a sustainable fishery in the future the same efforts should be made by Northern Pulp to ensure a sustainable fishery. At this point there has been no field trials, no lab test; absolutely zero work completed by Northern Pulp to prove to harvesters that they

will not be jeopardizing all the hard work going in to protect their lobster fishery. Considering lobster in the Gulf were worth $445 million in 2016, this warrants real science to be completed, not just literature searches based on 40 year old research.

Issue 19: "Scallop Buffer Zones SFA 22 and 24 are part of a system of Scallop Buffer Zones in SFA 21, 22, and 24 that covers a total area of 5,835 km^2 (DFO 2017). Scallop Buffer Zones were established to protect juvenile American lobster as they are known to contain lobster nursery habitat (DFO 2017). Scallop Buffer Zone SFA 22 is in the western Northumberland Strait, approximately 85 km to the west of the marine PFA. Scallop Buffer Zone SFA 24 is in the eastern Northumberland Strait and the effluent pipeline will cross through the Scallop Buffer Zone SFA 24 close to shore (Figure 8.12-10) in Caribou Harbour near Jessies Cove. The location of the outfall is outside this buffer zone" (page 384).

Figure 13 was shared in section 8.12.2.7 of the NPNS's environmental assessment. This image is inaccurate. According to Variation Order GVO-2017-087 (DFO 2017), "A one (1) nautical mile buffer zone will be closed until further notice from the nearest point of land in the counties of Cumberland, Colchester, Pictou and Antigonish and one (1) nautical mile from the nearest point of land around Pictou Island, situated in the Northumberland Strait." The outfall location would be within the scallop buffer zone is the zone was shown in his entirety. These scallop buffer zones are considered marine refuges by DFO and count toward the Marine Protected Area goal of 10% protection of coastal waters in Canada by 2020.

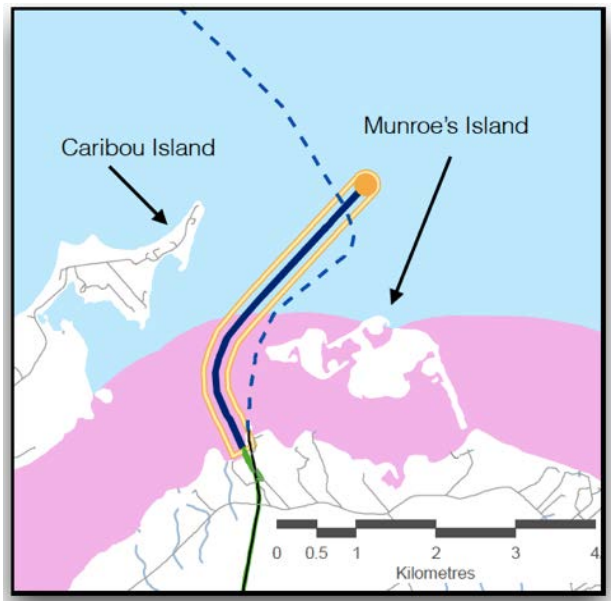

Figure 13: Outfall location and scallop buffer zone as shown, inaccurately, by Northern pulp in the Environmental Assessment

Recommendation 19: Ideally there would be no change or alteration to the scallop buffer zone. It is in place to protect juvenile lobster habitat and that protection zone should be honored.

Sincerely

Prince Edward Island Fishermen's Association, President

Maritime Fishermen's Union, President

Gulf Nova Scotia Fleet Planning Board, President

Andrea Paul
Pictou Landing First Nation, Chief

APPENDIX A. Ongoing Research Efforts by Industry

This section is designed to show the effort being made by the industry associations to improve the health of the oceans and eco-systems. It is not enough to maintain the current status of the ocean. The majority of current harvesters come from a long line of harvesters and the outlook for the future of the industry remains the same. Soon, the children of current harvesters will take over gear with visions of their own children doing the same.

It is not enough to consider the effects of the effluent on the ocean environment in one month or one year. Fishing has been going on for hundreds of years and should continue for 100 more. To ensure this is possible industry groups now work directly with the Department of Fisheries and Oceans (DFO) to come up with new management plans, help DFO collected required data for stock assessments and various research and help develop rebuilding plans for stocks. Below are a few of the projects industry works on with DFO to improve the health of our oceans:

Halibut Longline survey – Collaborative research with DFO. Collected data from this study feeds the Atlantic Halibut Stock Assessment.

Scallop survey – Collaborative research with DFO. This project is being completed to gain insight into changes seen in the scallops physiology.

Lobster/crab study – Rock crab is an integral part of the lobster's diet, unfortunately we don't know enough about the current rock crab biomass to ensure there will continue to be enough food for the lobster as their population grows. The project titled: "Effects of exploitation patterns and fluctuations in lobster (*Homarus americanus*) and rock crab (*Cancer irroratus*) abundances on lobster diet and condition in the Gulf of St. Lawrence; is the predator-prey interaction at risk?"; has been drafted and we are currently exploring funding opportunities to move forward. The project, if we are successful with funding, will be a collaboration between the Prince Edward Island Fishermen's Association, DFO and the Province of PEI.

Bio-collectors – This is a study that has been ongoing in the Gulf region for 10 years now and is a collaboration between the Prince Edward Island Fishermen's Association, DFO and the Province of PEI. This project gives us a look at the number of lobster settling in sites around Prince Edward Island at stage 4 to gather information on trends of higher or lower settlement annually. The hope of this project is to find a correlation between lobster settlement and lobster landings in the future. The collectors also provide an opportunity to collect data on some other species as well, including rock crab, mud crab, cunner and other fish species.

Lobster Node – This is an industry lead, pan-Atlantic group bringing DFO, industry and acedemia together to try to answer questions from the industry, specifically on lobster.

Bait Alternatives – foraging fish are normally used as bait in the lobster industry. These stocks are declining and fishers are, pre-emptively, looking for other sources of bait while they sit on working groups to come up with a plan to rebuild the stocks.

Temperature Probes in the Northumberland Strait – This is at the request of harvesters who are seeing bottom water temperature changes in the Northumberland Strait and they are curious if certain species will vacate the vicinity due to unsuitable habitat. This will be monitoring 10 locations in the Northumberland Strait for 6 months a year.

Acoustic Herring and variable mesh nets – Collaborative with DFO. This has been ongoing for many years to better understand the biomass of herring. The data is used to feed the stock assessment.

Dear Sir or Madam:

RE: Northern Pulp's Replacement Effluent Treatment Facility Project

I am writing to comment on Northern Pulp's proposed Replacement Effluent Treatment Facility Project.

I am a life long resident of Pictou County and have many ties to the Northumberland Strait. For over 40 years, my family has owned a cottage along the Northumberland Strait. I have spent each summer walking the beaches and swimming the waters. I have worked in Pictou as a lawyer for over 25 years and am a volunteer member of several boards and organizations in the area, including the Northumberland Fisheries Museum and Heritage Association, which is dedicated both to the preservation of fishing history and the celebration of the fishing culture. I am married to a commercial fisherman who fishes the waters of the strait, like many generations of his family who came before him. Involvement in the commercial fishery is a family commitment that is shared by our children and shapes our lives on a day to day basis. Like so many people in Pictou County and beyond, the Northumberland Strait is beloved by me and my family and is the cornerstone of our economic prosperity, social enjoyment and mental well being. The risk that Northern Pulp's proposed Effluent Treatment Facility Project poses to the Northumberland Strait and all who rely on it is simply too great for the Minister to grant approval.

Regulation 12 of the Nova Scotia *Environment Act* sets out the factors the Minister must consider when making her decision:

> 12 All of the following information shall be considered by the Minister in formulating a decision under subsection 34(1) of the Act:
>
> (a) the location of the proposed undertaking and the nature and sensitivity of the surrounding area;

(b) the size, scope and complexity of the proposed undertaking;

(c) concerns expressed by the public and aboriginal people about the adverse effects or the environmental effects of the proposed undertaking;

(d) steps taken by the proponent to address environmental concerns expressed by the public and aboriginal people;

(da) whether environmental baseline information submitted under subclause 9(1A)(b)(x) for the undertaking is sufficient for predicting adverse effects or environmental effects related to the undertaking;

(e) potential and known adverse effects or environmental effects of the proposed undertaking, including identifying any effects on species at risk, species of conservation concern and their habitats;

(f) project schedules where applicable;

(g) planned or existing land use in the area of the undertaking;

(h) other undertakings in the area;

(ha) whether compliance with licences, certificates, permits, approvals or other documents of authorization required by law will mitigate the environmental effects;

(i) such other information as the Minister may require.

Regulation 13(1)(e) made pursuant to the *Environment Act* states that one of the decisions of the Minister upon registration of a Class 1 undertaking may be as follows:

> "that a review of the information indicates that there is a likelihood that the undertaking will cause adverse effects or significant environmental effects which are unacceptable and the undertaking is rejected."

Section 34 (1) of the Nova Scotia *Environment Act* states that the Minister shall make one of six listed determinations upon the registration and review of an undertaking. I submit that, based on the factors listed in Regulation 12 set out above, it is appropriate that the Minister reject the undertaking as per section 34(1)(f) "because of the likelihood that it will cause adverse effects or environmental effects that cannot be mitigated."

ERRORS, MISREPRESENTATIONS, CONCERNS

In my review of Northern Pulp's proposed Replacement Effluent Treatment Facility (ETF) Project, I identified many errors, misrepresentations, and concerns. These are as follows:

1. Definitions: Commencing at Page xxiii, there are a number of words that are defined for the purposes of the proposal. Not all of the definitions used are the same as the definitions of the same terms used in relevant legislation, including the following definitions (emphasis are mine):

(a) **Contaminant** is defined in the *Environment Act* as: "contaminant" means, unless otherwise defined in the regulations, a substance that causes or may cause an adverse effect;

Contaminant is defined in the ETF proposal as: "A biological, chemical, physical or radiological substance that becomes harmful for humans or living organisms, when accidentally or deliberately introduced to air, water, soil or food."

(b) **Deleterious** substance is defined in the *Fisheries Act* as: deleterious substance means

> (a) any substance that, if added to any water, would degrade or alter or form part of a process of degradation or alteration of the quality of that water so that it is rendered or is likely to be rendered deleterious to fish or fish habitat or to the use by man of fish that frequent that water, or
> (b) any water that contains a substance in such quantity or concentration, or that has been so treated, processed or changed, by heat or other means, from a natural state that it would, if added to any other water, degrade or alter or form part of a process of degradation or alteration of the quality of that water so that it is rendered or is likely to be rendered deleterious to fish or fish habitat or to the use by man of fish that frequent that water,
> and without limiting the generality of the foregoing includes
> (c) any substance or class of substances prescribed pursuant to paragraph (2)(a),
> (d) any water that contains any substance or class of substances in a quantity or concentration that is equal to or in excess of a quantity or concentration prescribed in respect of that substance or class of substances pursuant to paragraph (2)(b), and
> (e) any water that has been subjected to a treatment, process or change prescribed pursuant to paragraph (2)(c); (substance nocive)"

Deleterious substance is defined in the ETF proposal as: "A substance that is dangerous and harmful."

(c) **Mitigate** is defined in the *Environment Act Regulations* as: "mitigate" means, with respect to an undertaking, to eliminate, reduce, or control the adverse effects or the significant environmental effects of an undertaking, and may include restitution for any damage to the environment caused by such effects through replacement, restoration, compensation or any other means;

Mitigation is defined in the ETF proposal as: "With respect to a project, refers to the elimination, reduction or control of the adverse environmental effects of the project and includes restitution for any damage to the environment caused by such effects through

replacement, restoration, compensation or any other means."

(d) **Significant** is defined in the *Environment Act Regulations* as: "significant" means, with respect to an environmental effect, an adverse effect that occurs or could occur as a result of any of the following:

(i) the magnitude of the effect,
(ii) the geographic extent of the effect,
(iii) the duration of the effect,
(iv) the frequency of the effect,
(v) the degree of reversibility of the effect,
(vi) the possibility of occurrence of the effect;

Significance is defined in the ETF proposal as: "A defined threshold of acceptability. The significance of adverse environmental effects is determined by a combination of scientific data, regulated thresholds, standards, social values and professional judgment. For example, the ecological context of a project may be determinant of whether likely adverse effects are significant."

It is noted that the term "**adverse effect**" is not defined in the ETF proposal. It is defined in the *Environment Act* as " an effect that impairs or damages the environment or changes the environment in a manner that negatively affects aspects of human health".

Also noteworthy is the definition of the term "**reach**" in the ETF proposal. It is defined as, "In the context of this project, a reach is a section of watercourse of defined length (usually 100 m) in which fish and fish habitat surveys are completed, and water quality measurements are taken." The term "reach" is not defined in the *Environment Act*, regulations or other applicable legislation.

Because the ETF proposal uses definitions which are different than those set out in the relevant legislation, when the proposal reaches a conclusion or makes a statement, the standards for that conclusion or statement may not be what is set out in the legislation. The conclusion or statement may satisfy the definition the ETF chooses to apply, but it may not satisfy the standard set out in the actual legislation.

Also of concern is the definition of "**change in water quality**" found on page 346 of the ETF proposal, which states, "For the purposes of this assessment, a change in water quality refers to any alteration to pH, dissolved oxygen (DO), temperature, total suspended solids (TSS) or contaminants in the water column." The definition does not include such things as AOX, BOD, COD or colour.

The definition of "**change in marine fish population**" set out in the proposal is also of concern. On page 384, a change in marine fish population is said to "include any physical injury or mortality on fish attributable to the project, and any destruction or alteration of habitat from disturbance of the marine environment." It is not clear whether this definition includes such things as bio-accumulation and any other effect or change to fish.

2. The ETF proposal states that the temperature of the treated effluent will reach ambient termperatures within 2 meters of the diffuser and therefore will comply with CCME Guidelines for temperature . This is a misrepresentation of the CCME Guidelines (Canadian Water Quality Guidelines for the Protection of Aquatic Life - see attached), which state, "Human activities should not cause changes in ambient temperature of marine and estuarine waters to exceed +/- 1degree Celsius at any time, location, or depth."

3. On page 123 of the proposal, it is stated that, "Dioxins and furans in NPNS's effluent have virtually been eliminated since the conversion to chlorine dioxide bleaching in 1998. NPNS has never exceeded the limits as per the Pulp and Page Mill Effluent Chlorinated Dioxins and Furans Regulations. In fact, dioxins and furans testing for the last 5 years has consistently shown that all of the compounds required to be tested under the regulations have not been detected in NPNS' effluent (non-dedect)." This statement runs contrary to the test results of samples taken June 11, 2014 from NPNS' effluent leak. The test results are published on NSE's website and attached hereto. The test results appear to reveal that there were exceedences of dioxins and furans beyond what is permitted under the Pulp and Paper Effluent Regulations.

4. On page 433 of the proposal, the physical land use in the vicinity of the land-based portion of the effluent pipeline route is set out. There are a number of land uses missing from this list, including single family homes and cottages in the area between the causeway and Division Road, and near the ferry wharf. Also in the vicinity of the ferry wharf and missing from the list are the Caribou fishing wharf, the fishing wharf at North Nova Seafoods, the North Nova Seafoods fish plant, and the Pictou Island ferry. At the fishing wharves, the uses extend beyond the tying up of fishing vessels. At the wharves is where fish buyers set up their buying stations for various fisheries and store bait and catches. It is where fishers work on their vessels and gear. Fishers use water from the Northumberland Strait to wash down their vessels and hydrate and store their catches. The wharves are used by recreational boaters, barges and tugs and those seeking shelter from storms or rough seas. The proposal puts all of these uses at risk.

The ferry service between Caribou, Nova Scotia, and Wood Islands, Prince Edward Island, is a vital link between the two provinces. Any infrastructure or impediment to the use or expansion of the ferry wharf at Caribou should not be permitted. The proposal does not set out details as to the specific location of the proposed effluent pipe. Insufficient details are provided to determine whether the proposed pipe will impact the ferry service now or in the future. The attached article from CBC dated May 5, 2017 confirms that changes to the ferry service are being contemplated.

5. The proposal claims that "operation of the outfall will not interact with use of community beaches in the surrounding area." (see page 440). This statement appears to contradict the results of the Stantec Final Caribou Discharge Receiving Water Study found in Appendix E1 which shows effluent concentrations washed ashore in various areas. For example, Figures 2.7 and 2.9 shows effluent on the beach at Munro's Island which is a popular provincial park. Figure 2.11 shows effluent on a beach at Caribou Island which is enjoyed by many locals, cottagers and tourists. I suggest that the presence of effluent in any form on any beach or shoreline will interact

with the use of community beaches.

6. On page 505 of the proposal, it is stated that "Stantec (2019) also reported that ambient air monitoring data for 2015, 2016 and 2017 showed no exceedances of the applicable Nova Scotia regulatory AQC for the air contaminants monitored under the NPNS approval to operate." This does not appear to be a true statement. Attached is Source Emission Test Results for Winter 2015 and Summer 2015. Both tests were conducted by Stantec and the results were found on NSE's website. The test results show exceedances for both the recovery boiler and the power boiler as outlined in the company's industrial approval.

7. The proposal claims that "the loss of vegetation and associated bird habitat within the pipeline footprint area along the road shoulder (if it occurs) will be consistent with existing road maintenance activities along Highway 106 and thus, will not result in any additional loss of bird habitat." (see page 561). This statement fails to consider the habitat of the double breasted and great cormorant which are located along the Harvey A. Veniot Causeway. Their habitat will be destroyed with the construction of the pipeline, and will not likely recover.

8. The proponent's public consultation was not adequate. I attended the open houses in New Glasgow and Pictou Landing which were both held prior to the new route of the pipe to Caribou Harbour being announced. The open houses were conducted on the basis of the pipe going into Pictou Harbour. No open houses were conducted following the announcement of the new route to Caribou, even though Dillon Consulting Limited promised me in two letters that they would hold additional open houses. Dillon also promised me in the same correspondence that they would release studies to the public as they became available. Very few studies were released to the public prior to the registration of the proposal. The correspondence from Dillon are included with Ecojustice's submission to the proposal on behalf of Friends of the Northumberland Strait.

The open houses were crowded, loud, and not conducive to conversation, asking questions or obtaining information. They did not allow for meaningful discussion and it was difficult to engage the proponents. They did not have any means of taking notes of my concerns for future reference, consideration or documenting purposes.

The information provided at the open houses, in a subsequent mail out and advertisements represented that the project would include an oxygen delignification system which would improve the quality of the effluent. This system does not appear to be included in the proposal. There was no consultation by the proponent with the public following the announcement of the new route or the elimination of the oxygen delignification system from the project.

9. I am concerned that the environmental assessment is proceeding on the basis of a Class 1 environmental assessment which limits the time the pubic has to respond to the proposal. The proposal is almost 1700 pages long and takes a lot of time to read, analyse and reply. Because of the short length of time provided, I submit that the pubic consultation is not meaningful or as fulsome as it could otherwise be. This raises significant public policy concerns which are exacerbated by the lack of input the public will have to the additional information and studies the proponent has stated it will file at a later date. Pubic review and input is vitally important to the EA process but the public is not being this opportunity.

Missing Information

Aside from the many studies yet to be completed, the proposal is missing several pieces of information, as follows:

(a) The proposal states that the proponent's "Toxicity Prevention and Remediation Plan" will be used. This plan was not included in the proposal, and as such, it is not possible to determine whether it is complete or effective. Any reference to this plan and its use to mitigate or address any issue should not be considered.

(b) Page 28 of the proposal refers to a brochure attached to Appendix D. No such brochure is attached.

(c) Page 349 and 351 makes reference to "occurring in a context of previous disturbance". There is no information provided as to what the previous disturbances refers to.

(d) Page 460 sets out 10 known ship wrecks in the vicinity of the marine PFA/LAA. Attached is a list of 17 ship wrecks which I found after searching the Marine Heritage Database if the Maritime Museum of the Atlantic which is the same database the proponent claimed to have used.

(e) There appears to be information missing from Table 11.1-1 (page 535) as not all VEC's set out in section 8 of the proposal are summarized.

(f) Appendix Q (Bird Data) sets out data collected for the month of December only. As such, any data from migratory birds who left the area by December is not captured.

(g) The proposal fails to disclose that the location of the new on-site ETF will be located adjacent to Canso Chemicals which is a former chemical plant that has known deposits of mercury on its property. The proposal does not address the potential interaction that the presence of mercury will have on the construction and operation of the ETF and the environment.

(h) Although the proponent appears to imply that the lack of cooperation from fishers is the reason for the deficiencies in the proposal's information relating to commercial fishery in the area, it must be noted that area fishery information is contained in the most recent Environmental Effects Monitoring Study (EEM), which is attached as Appendix J of the proposal. The Receiving Waters Study completed by Stantec (attached as Appendix E2 of the proposal) sets out less information on the area fishery than the EEM study which was prepared prior to the Receiving Water Study. Also, during the open houses I attended in both New Glasgow and Pictou Landing hosted by the proponent as part of this environmental assessment process, I personally witnessed fishers and others drawing on a map the location of the fishery and explaining in detail the location of the area fishery to the proponent. The proponent appears to have disregarded this information as it has not been included in the proposal.

(i) A provision in the sign off sheet contained in the Receiving Water Study found in Appendix E3 of the proposal limits the usefulness of the study. The provision states, "The material in it [the Receiving Water Study] reflects Stantec's professional judgment in light of the scope, schedule and other limitations stated in the document and in the contract between Stantec and the Client." Unless the contract between Stantec and KSH (the Client) is disclosed, it is not possible to understand the effect that the "scope, schedule and other limitations" imposed in the contract may have had on the results of the Receiving Water Study. As such, the Receiving Water Study ought not to be relied upon in the review of the proposal.

(j) On page 336 of the proposal, the marine local assessment area (LAA) is said to consist of a corridor approximately 300 m wide, including an area of 300 m encircling the outfall. There is no explanation as to how this area was determined or developed. It appears to be an arbitrary area with no basis for its existence.

CONCLUSION

This proposal was submitted prematurely without proper study or consideration for the environment and the adverse effects of the proposal on the Northumberland Strait. On page 12 of the proposal, the proponent admits that "due to EA Registration submission timing, the study period did not facilitate full biological field assessments for the current proposed transmission pipeline corridor", and "...it was not possible to conduct field work in the new pipeline corridor or marine environment in order to inform this EA Registration." The time constraints were created and were self imposed by the proponent. They could have chosen to complete the required studies and then file the proposal. Failure by the proponent to do so, and acceptance by the minister of this tactic if the proposal is approved, sets a very dangerous precedent for future EA registrations. It would convey the message that EA registrations do not need to be complete at the time of registration. Instead, a proponent can file an incomplete EA, receive approval, and then complete important studies. These studies would be filed without public review and input which would eliminate a vital component of an EA. This is not acceptable and is against public policy and violates procedural fairness.

I suggest that the proposal ought not to have been accepted for registration because it was not complete. Regulations 9(1A) made pursuant to the *Environment Act* states that the proponent must submit, "environmental baseline information". This was not included in the proposal.

To protect the integrity of the EA process in Nova Scotia, this proposal must be rejected. The proponent must start the process from the beginning once it has gathered the required environmental baseline information and all studies required to properly review it's proposal. The precautionary principle, set out in section 2(b)(ii) of the Environment Act, ought to be followed. It states,

> "(ii) the precautionary principle will be used in decision making so that where there are threats of serious or irreversible damage, the lack of full scientific certainty shall not be used as a reason for postponing measures to prevent environmental degradation."

The environmental effects which would occur as a result of the proposal cannot be mitigated.

The proposal suggests that fishers can be compensated and therefore mitigation will be served. Money cannot address the harm that this project will bring because there is more than monetary or commercial issues at play. Money cannot compensate for the loss of a beloved beach or shoreline. Money cannot compensate for the loss of peace and enjoyment of a day on the strait with family and friends. Money cannot compensate future generations of fishers who want to fish the pristine waters of the strait. Money cannot compensate a rural community who is dependent on the strait for its economic prosperity, social well being and mental health.

This project must be rejeted because of the likelihood that it will cause adverse effects or environmental effects that cannot be mitigated.

Yours truly,

Canadian Water Quality Guidelines for the Protection of Aquatic Life

TEMPERATURE
(Marine)

Water temperature, along with salinity, is one of the most important physical factors affecting marine and estuarine organisms. Temperature affects almost every physical property of seawater. The ionization constant, surface tension, and latent heat of vaporization decrease in a near-linear fashion as temperature is raised. The compressibility, viscosity, and specific heat of water all decrease nonlinearly with increasing temperature. Vapour pressure and thermal conductivity, the speed of sound in seawater, its electrical conductivity, and osmotic pressure, however, increase in magnitude as temperature increases. The solubility of gases, such as nitrogen, hydrogen, carbon dioxide, and oxygen, in contrast, all decrease as water temperatures rise (Cox 1965; Houston 1982).

Temperatures in the Canadian Pacific and Atlantic coastal and estuarine waters vary considerably depending on location, depth, freshwater inputs, extent of ice formation, upwellings, and currents (Dera 1992). For both coasts there is a pronounced seasonal variability in nearshore surface temperatures. Temperature measurements along the Canadian Atlantic coast have shown that winter water temperatures often range between -2 and 6°C, while summer temperatures vary between 7 and 18°C (Petrie and Jordon 1993). In the Straits of Georgia and Juan de Fuca, along the Canadian Pacific coast, winter temperatures between 5 and 8°C have been measured, while summer temperatures have been between 12 and 15°C (Thomson 1981). These general water temperature ranges are often exceeded in localized areas, such as certain fjords in British Columbia (e.g., Pendrell or Hotham Sound), where summer stratification has caused surface temperatures to exceed 20°C (Valiela 1979; Thomson 1981). Temperatures in the Arctic Ocean also exhibit geographical, seasonal, and annual variations, but fluctuations are smaller than those experienced in the Pacific or Atlantic Canadian coastal waters. In areas with drifting ice, surface waters usually remain at about -1.8°C, year-round. In the summer, ice-free areas may reach temperatures that rise several degrees above 0°C (Heimdal 1989). In northern Baffin Bay, average monthly temperatures over a 2-year period changed only marginally from a low of -1.53°C to a high of 0.19°C (Ross 1991). Ice and water transport patterns, winter air temperatures, and freshwater inputs can contribute to considerable local variability in recorded Arctic marine water temperatures (Drinkwater 1986; Prinsenberg 1986; Hopky et al. 1990).

Most of the human activities that affect the temperatures of marine and estuarine waters in Canada are associated with the release of waste heat. The major sources of these inputs include the processes of the chemical, petrochemical, and pulp and paper industries; municipal sewage; and thermal generating stations (Swiss 1984). Thermal generating stations account for over 75% of the total heat discharged into the marine environment. For example, the six thermal stations in Nova Scotia have been observed to raise the temperature of their effluent between 6.1 and 14.4°C over natural levels (Swiss 1984).

Other disturbances of aquatic temperature regimes may be related to the physical alteration of a water body. For instance, such processes as river diversions, water withdrawals from coastal areas, retaining walls in estuaries, large jetties, breakwaters, and causeways in coastal areas may significantly alter water temperatures. The construction of a tidal barrage in the upper regions of the Bay of Fundy, for example, increased the local tidal range and resulted in an overall lowering of the area's surface sea temperatures (Greenberg 1984).

Biological Effects

Summary

Temperature affects many chemical and biological processes. Chemical equilibrium constants, solubilities, and the rates of chemical reactions are temperature-dependent (Whitehouse 1984). Most marine and estuarine organisms are poikilotherms (i.e., cannot regulate their internal temperatures). As a result, biological processes, such as photosynthetic and respiration rates, spawning, uptake of toxic substances, and behavioural patterns of organisms, are all responsive to changes in temperature (Strickland 1965; Houston 1982; Aiken and Waddy 1990).

Kinne (1963) conducted a comprehensive review of the effects of water temperature on marine and brackish water animals. The results of this review indicated that biological processes may be greatly affected by water temperature fluctuations, gradients, ranges, and averages, as well as by the frequency and intensity of changes, duration of patterns, and accumulated heat units. Most marine and estuarine species, or populations within species, have characteristic tolerable temperature ranges

that include specific high and low lethal temperatures. Eurythermal species, i.e., species that can tolerate wide ranges of temperatures, are characteristic of aquatic environments with fluctuating temperatures. Stenothermal species, i.e., species that can only exist in a narrow range of temperatures, are characteristic of environments with near-constant temperatures. Gradual water temperature changes are usually better tolerated by all species than sudden changes (Kinne 1963).

Many marine and estuarine organisms can adjust to alterations in ambient water temperatures through an array of biological responses. This process, termed acclimation, can include behavioural, morphological, physiological, or biochemical responses. The length, frequency, and severity of exposure, as well as thermal history, are all-important determinants of an individual organism's response to temperature changes (Fry 1971; Hochachka and Somero 1971; Thompson and Newell 1985).

Potential effects of extremely low water temperatures on aquatic organisms include insufficient integration of nervous and metabolic processes, insufficient rates of energy liberation, changes in water and mineral balance, increase in osmoconcentration resulting from extracelluar freezing followed by the dehydration of cells, liquefaction of cortical protoplasm, and gelation of the cell interior (Kinne 1963). Many species of marine fish have body fluids with lower osmotic pressure than seawater, causing such species to freeze at temperatures above the freezing point of seawater. Most species of marine fish avoid freezing by either avoiding ice-laden seawater and/or by increasing the osmotic concentration of their blood (DeVries 1971).

The effects of extremely high temperatures include insufficient supply of oxygen, failures in process integration, desiccation (intertidal organisms), enzyme inactivation, change in lipid state, increase in protoplasmic viscosity, increase in cell membrane permeability, protein denaturation, and release of toxic substances from damaged cells. Death can result from exposure to either extremely high or extremely low water temperatures (Kinne 1963).

Water temperature changes that are not lethal can produce a wide variety of significant sublethal effects. For example, temperature changes can significantly affect photosynthesis; respiration; susceptibility to disease; osmoregulation; uptake of pollutants; susceptibility to the toxic effects of pollutants; various behavioural patterns, including physical activity, reproduction, feeding, growth, migration, distribution, intra- and inter-specific competition, predator–prey relationships, community composition, and parasite–host relationships; and many other biological processes (Kinne 1963). Selected examples of some water temperature effects in marine and estuarine ecosystems follow. Wherever possible, examples dealing with Canadian marine or estuarine systems were selected.

Specific Effects

Lüning and Freshwater (1988) studied the water temperature tolerance (-1.5–30°C) of marine algae (49 species) and seagrass (two species) near Vancouver Island. All species studied showed high levels of cold tolerance, with all surviving at 0°C and only six species dying at -1.5°C. Heat tolerance was much more variable; most subtidal species showed survival limits lower than 20°C; intertidal species survived at higher ranges of 20–28°C. Only one species, the seagrass *Zostera marina*, survived at 30°C. The authors characterized the northeast Pacific seaweeds as "cold-stenothermal", indicating a narrow range of temperature tolerance at the low end of the range of global marine temperatures.

Different organisms will exhibit different productivity levels at a given water temperature range. In Newfoundland coastal waters, Pomeroy and Deibel (1986) measured low levels of bacterial growth and respiration during the spring phytoplankton bloom, when surface temperatures were -1–2°C. It was suggested that in very cold environments, low bacterial activity (i.e., decomposition) during a period of high primary production could result in greater food availability for herbivores, thereby enhancing secondary production. Temperature-related control of bacterial activity may therefore be important in influencing production at higher trophic levels (Pomeroy and Deibel 1986; Pomeroy et al. 1991).

Water temperature plays a limiting role on the feeding and recruitment success of fish and crustacean larvae. The eggs of the walleye pollock *(Theragra chalcogramma)* in the Bering Sea generally hatch at temperatures ranging between 3 and 6°C, and the larvae feed on copepod nauplii. It was found that the larvae reared at 5.5°C were more successful at capturing copepod nauplii when the prey was at low concentrations, than the larval fish cohorts reared at 3°C. Conversely, larvae hatching at 5°C required 8% more calories than those hatching at 3°C (Paul 1983 and references therein). Paul and Nunes (1983) reported that northern pink shrimp larvae *(Pandalus borealis)* that hatched during a warm year (i.e., at 6°C) required 63% more calories to meet their metabolic requirements than larvae of the same weight that hatched in a cooler year (i.e., at 3°C). If this increased metabolic requirement were to exceed their ability to find and ingest food, the survival of that year's recruits could be compromised.

Increasing water temperature generally causes increases in the respiratory rates of aquatic animals and vascular and nonvascular plants (Kinne 1963; Dawson 1966). Beyond a given temperature, thermal stress is induced (Kinne 1963; Paul and Nunes 1983; Paul 1986; Paul et al. 1988). As respiratory rates increase, so do the organism's metabolic energy needs (feeding or photosynthesis). This relationship has important implications for the overall productivity and survival of marine and estuarine organisms that thrive in habitats with varying temperature regimes. Commercially important pacific fish species were investigated for their metabolic oxygen requirement. In the linear portion of the oxygen consumption-temperature relationship, the nonfeeding metabolic requirement increased by 11%, 7–12%, 9%, and 18% per °C for Pacific cod, Atlantic cod, saffron cod, and juvenile walleye pollock, respectively (Paul 1986; Paul et al. 1988, 1990, and references therein).

Water temperature may also affect the reproductive capacity of marine organisms. Tanasichuk and Ware (1987) found that for Pacific herring the mean sea temperature in overwintering habitats during the three months before spawning (December to March) best accounted for variations in size-specific fecundity. The range in mean monthly sea surface temperature during the three months before spawning for the five years studied was 5.6–8.1°C. This range is relatively narrow, considering that the data purposely included one year that was very strongly influenced by an El Niño episode, and that herring came from seven sites extending close to 700 km along a north–south axis (Tanasichuk and Ware 1987).

All the relationships previously described demonstrate that relatively small changes in the extent and timing of temperature phenomena in high-latitude coastal waters can significantly alter biological processes.

Temperature and Toxic Substances

In general, the sensitivity of aquatic organisms to toxic substances increases with increasing water temperature (Cairns et al. 1975). The interactions between temperature and toxicity, however, are very complex because temperature generally affects the chemistry and availability of toxic substances, the survival and function of organisms, and the responses of organisms to toxicants. In water, ammonia exists in two forms, a non-ionic species (NH_3) and an ionic species (NH_4^+). The toxicity of ammonia to aquatic organisms is largely determined by the concentration of the non-ionic species, which is partly temperature dependent. A decrease in temperature will lead to an increase in the proportion of NH_3 in water (Whitfield 1974; Miller et al. 1990).

Some criteria or guideline documents state different maximum or average toxicant concentrations allowed or recommended for different temperatures. The British Columbia ambient water quality criteria for ammonia for the protection of marine life (Nordin 1992, adopted from USEPA 1989) give maximum and average concentrations of total ammonia nitrogen that vary with water temperature.

According to Voyer and Modica (1990), insufficient data exist to permit the development of relationships between either water temperature or salinity and the toxicity of heavy metals in marine water. However, the authors also stated that evidence is available that indicates that survival, bioconcentration, and sublethal effects of pollutants on estuarine organisms are often related to ambient salinity and temperature conditions. Generally, as water temperature increases, the rate of metabolic processes increases, resulting in enhanced uptake and toxicity of metals to marine and estuarine organisms (Phillips 1976; Waldichuk 1985; McLusky et al. 1986; Voyer and Modica 1990).

Interim Guideline

Human activities should not cause changes in ambient temperature of marine and estuarine waters to exceed ±1°C at any time, location, or depth. The natural temperature cycle characteristic of the site should not be altered in amplitude or frequency by human activities. The maximum rate of any human-induced temperature change should not exceed 0.5°C per hour (CCME 1996).

Rationale

Many biological processes that occur in marine and estuarine waters are sensitive to temperature changes. The interim guideline of ±1°C for induced temperature change is recommended to ensure that adverse effects on these processes are minimized. The variability of coastal and estuarine waters is such that this temperature alteration is probably a minor proportion of the total variability to which organisms are exposed in these environments. Furthermore, the recommended rate of temperature change of 0.5°C per hour, which is adopted from the Alaskan guideline for temperature (BNA 1986; State of Alaska 1989), should reduce the impact of sudden induced temperature changes on the Canadian marine environment.

Site-specific diurnal, seasonal, and annual water temperature regimes are intended to be maintained through the recommendations of the interim temperature guideline. In recognition of this intention, a clause, adapted from the USEPA (1986) and Alaskan (BNA 1986; State of Alaska 1989) guidelines, which calls for the preservation of the amplitude and frequency of ambient temperature cycles, has been included as part of the Canadian interim temperature guideline.

It is recognized that, in implementing the recommended interim guideline for temperature, allowance may be made for the existence of mixing zones. Definitions of mixing zones are generally site-specific and consider the requirements of the jurisdiction or jurisdictions responsible for a particular activity.

Northern Pulp Effluent Leak NSE test results - samples taken June 11, 2014

The following test data was taken on June 11, 2014, after an effluent leak at Northern Pulp. The wetlands were the most affected by the leak, and the evidence shows that materials likely did not reach Melmerby Beach and other points downstream from where the leak occurred **Definitions:** pg is picogram (one trillionth of a gram); ug is microgram (one millionth of a gram), and mg is milligram. ND = not detected. Dioxins and Furans (below the blue line) were compared to federal pulp and paper effluent regulations (PPER). Exceedances to the operating approval (blue) will be dealt with in accordance with the department's compliance model. It should be noted that despite BOD and TSS exceeding approval limits, results of toxicity testing determined the exceedances were non toxic. Dioxins and Furans were compared to PPER exceedences (red) and fall under the jurisdiction of Environment Canada.

*Calculated based on 90,000 cubic metres per day flow

**Lab used fresh water rather than marine species for testing. Samples had passed the acceptable hold period by time the lab discovered the error, however based on the fact samples at SW2 have higher concentrations of effluent than those at SW1 or SW3, it can be concluded that the effluent would have a reduced impact once diluted.

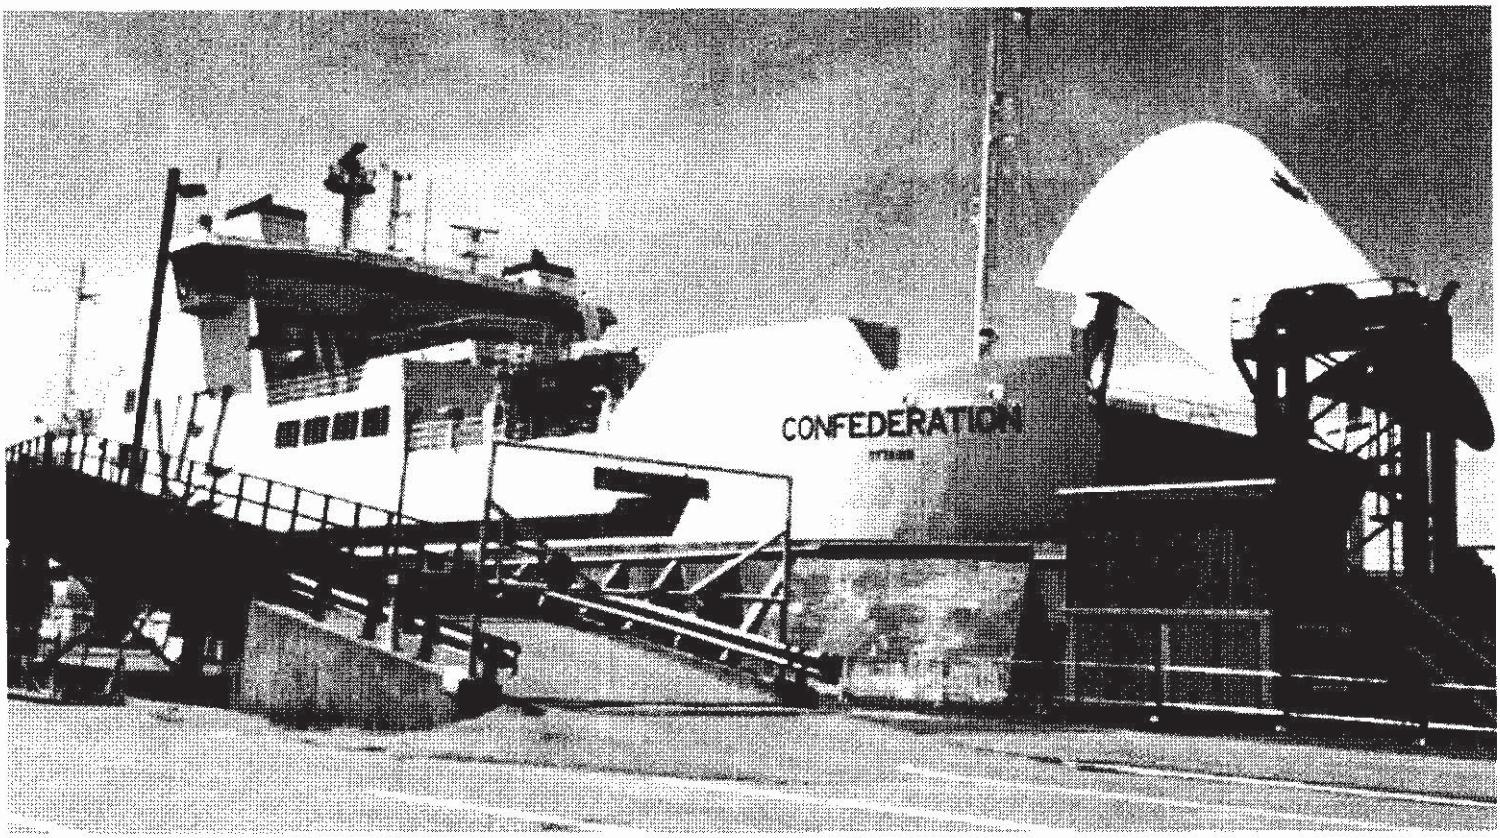
***PPER - Federal Pulp and Paper Effluent Regulations require dioxins and furans to be non-detectable. This is enforced by Environment Canada.

CBC

New ferries, new operators, part of proposed revamp of Maritime ferries

Proposal would see operator-owned ferries on the water

Kevin Yarr · CBC News · Posted: May 05, 2017 7:11 AM AT | Last Updated: May 5, 2017



The Confederation was left alone to serve the Northumberland Strait, offering limited sailings for most of last season. (Julia Cook/CBC)

A federal government proposal could see new operators for three ferry services in the Maritimes, new ferries, and big changes to the way the services operate.

The government made the announcement at the community centre in Belfast, in eastern P.E.I., Friday morning.

The affected services connect

- Wood Islands, P.E.I., and Caribou, N.S.
- Souris, P.E.I., and Îles de la Madeleine, Que.
- Digby, N.S., and Saint John, N.B.

"I am very pleased that the Government of Canada is seeking to move towards long-term contracts to provide stability and certainty in the communities of eastern Prince Edward Island, which in turn will stimulate our economy," said Cardigan MP Lawrence MacAulay in a news release.

MacAulay said the proposal opens up the contract process in a way it has never been before.

Northumberland Ferries, the current operators of the P.E.I. — Nova Scotia service, welcomed the announcement of a strong, long-term commitment in a news release sent out after the announcement.

"We are pleased, for our customers, our employees, and the communities we serve, that the Government of Canada is making a strong and long-term commitment to the Wood Islands/Caribou and Saint John/Digby ferry services," said Chairman and CEO Mark MacDonald in a statement.

New operating structure proposed

Before that announcement, in the early morning hours of Friday, the government posted a request for information from industry that outlined its plans.

Ottawa is looking to move away from the current model where it owns the ferries and leases them to the companies that operate the services. The proposal is for the operating companies to own the ferries and sign a long-term contract — perhaps as long as 20 years — to provide the service.

Long-term contracts will provide economic stability, says P.E.I. MP Lawrence MacAulay (Adrian Wyld/Canadian Press)

The proposal is currently at a request for information stage, with the government seeking feedback from companies.

As it stands, the government plan would see at least of three of the four ferries on the three routes replaced within the next three years. Ottawa is offering up the *MV Fundy Rose*, which service the Saint John – Digby route. Purchased in 2015 for $44.6 million, the *Fundy Rose* was built in 2000.

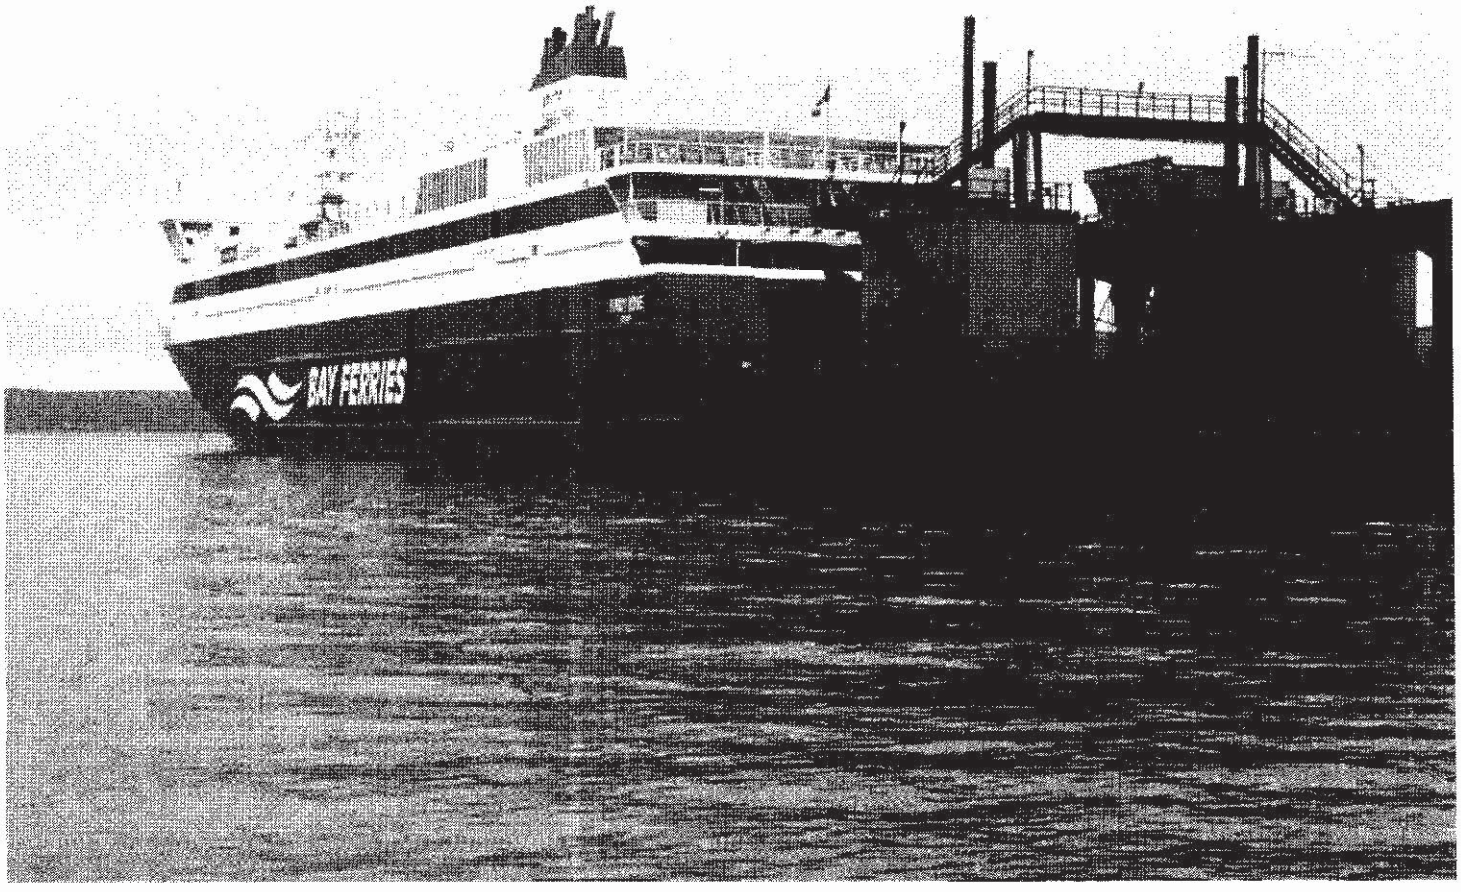
- **Fundy Rose ferry between Saint John and Digby unveiled**

The government says it is interested in leasing out the other ferries for a transition period of up to three years. Those ferries are

- *MV Confederation*: Built in 1992, serving the P.E.I.- N.S. route.
- *MV Holiday Island*: Built in 1971, serving the P.E.I.- N.S. route.
- *MV Madeleine*: Built in 1981, serving the Souris Îles de la Madeleine route.

Vessels new to the routes would be no more than 10 years old.

The most recent federal budget included $278 million over five years for the service, about $18 million more than the previous funding agreement. In August Prime Minister Justin Trudeau said his government was committed to supplying the ferry service.



Ottawa is offering up the MV Fundy Rose as an option for the Digby - Saint John route with the new contract. (Roger Cosman/CBC News)

The government will hold an industry day for discussions on the proposals in Gatineau, Que., on June 2, and is scheduling one-on-one meetings with companies between July 10 and 21. It is accepting comments on the proposals until July 31.

Last summer the aging ferries connecting the Island and Nova Scotia struggled to stay on the water. The *Holiday Island* was in dry dock most of the season, leaving the *Confederation* alone to serve the route through the busy July-August season.

Northern Pulp Nova Scotia mill, in Abercrombie, Pictou County
Source Emission Test Results for Winter 2015

The table below provides an overview of the results of the stack testing (source of the emissions) conducted on the Northern Pulp mill. The testing was conducted by Stantec Consulting Ltd., during the week of March 9, 2015.

Stack tests were taken at two locations: recovery boiler and power boiler

At the time of testing, stack emissions on the recovery boiler were 833 mg/Rm3, which is well above the stack emission limit of 375 mg/Rm3 as outlined in the company's industrial approval with the province. Emission levels for particulate on the power boiler were 155 mg/Rm3, which is above the approval limit of 150 mg/Rm3.

Northern Pulp Nova Scotia mill, in Abercrombie, Pictou County
Source Emission Test Results for Summer 2015

The table below provides an overview of the results of the stack testing (source of the emissions) conducted on the Northern Pulp mill. The testing was conducted by Stantec Consulting Ltd., during the period of September 15-18, 2015.

Stack tests were taken at two locations: recovery boiler and the power boiler.

At the time of testing, emissions of particulate matter from the recovery boiler was 3.9 mg/Rm3, which is well below the stack emission limit of 77 mg/Rm3 as outlined in the company's 2015 industrial approval. Results for the power boiler were 190 mg/Rm3 which is above the emission limit of 150mg/Rm3.

Subject: In support of Northern Pulp"s EA application
Date: March 9, 2019 12:40:19 PM

I am writing in support of the Environmental Assessment application submitted by Northern Pulp for its new treatment facility.

A lot has been said about Northern Pulp and its impact on the local community. I stand in agreement with many, including Unifor, that Boat Harbour must close and be cleaned up to respect Pictou Landing First Nations people and their land. I also know there are many positives about having 300 good-paying jobs in Pictou, supporting thousands more across Nova Scotia, particularly in rural communities.

The Nova Scotia Environment Act is an essential piece of legislation designed to protect our shared environment and guide our economic development. The Act rightly spells out its purpose through a set of principles for sustainable development that should guide its application, including:

------> The linkage between economic and environmental issues, recognizing that long-term economic prosperity depends upon sound environmental management and that effective environmental protection depends on a strong economy.

In this situation, science should determine the best path forward. Nova Scotia, along with the rest of Canada, has among the highest global standards for environmental stewardship in the forestry sector.

The job of government and every person we elect to represent us in government is to find the best way forward when there are many competing and sometimes opposing interests. Communities across Canada manage to find a fair balance where good mill jobs coexist with a prosperous fishing industry and thriving communities.

We can and must find this balance for Pictou. There is a lot at stake: jobs, the environment, and respect for First Nations. We can and must find a solution that supports all three.

Thank you.

Hello,

Attached is a letter concerning Northern Pulp.

Thank you.

Dear Minister Miller,

I am writing to you regarding Northern Pulps Replacement Effluent Treatment Facility Project.

My name is and I live just outside on Pictou, Nova Scotia, in the small community of . I have lived in this area for all of my years. I am a commercial fishing license holder, for years fishing out of Toney River, Nova Scotia, and also fished in the area long before purchasing my own license. The threat of this new project impacts me and my family a great deal. Not only am I employed in the commercial fishery, but my father is also a commercial license holder and my brother, and son are both currently employed in the fishery. My family has been fishing in this area for many years and have depended on the Northumberland Strait for an income, but it is also a key to our way of life and culture. My family is not the only one with this sort of bloodline dependency and history with the fishery and the Strait. My community is full of people who depend on the Strait for survival. The Northumberland Strait is more then just a body of water, it is our life.

I wish to raise a couple points of concern with the project.

First, as a fisherman I am concerned, that the proposed effluent pipe will be a detriment to the local fisheries, including that of lobster, rock crab and herring. The proposed outfall location is premium breeding grounds for all of these fisheries, and are of grave importance to the local area, as well as the entire economy of Nova Scotia. I feel as though there should be a greater deal of importance placed on protecting these fisheries. The science provided in Northern Pulps proposal is outdated, being conducted in the 1960's. Our industry is under constant pressure to evolve and become more sustainable and improve our fishing methods as well as our conservancy methods. How can a large corporation, who is not even Canadian owned, come in and attempt to infiltrate our waters, and not be subject to more severe outside pressures to ensure that what they are doing is not only scientifically acceptable but also morally right. Just because they claim that the effluent technically passes whatever loose requirements imposed by the federal pulp and paper mill guidlines, does not mean that is morally right to be pumping anything into the ocean. All levels of government have been claiming that we need to protect the ocean, that we need to cut down on pollution and begin to care for our environment because we won't have it forever. How can someone say this but then consider pumping effluent full of toxins into the ocean. The Government can't have it both ways and are going to have to step up to the plate. Is big industry more important than the health and well being on not only the Environment and ecosystem of the Northumberland Strait, but as well as the health and well being of the people that live there. Nova Scotia is considered Canada's ocean playground, and that's for good reason, the province is surround by the ocean. But what happens if Northern Pulp wants to start pumping their effluent into that playground? No ones going to want to play there anymore.

A separate point I would like to bring up is the monitoring of the pipe and its wellbeing. My main point being that how will the pipe be monitored? They claim that the accidental release of effluent can occur. There is an example of this in the fall of 2018 when a ruptured pipe was

discovered by a passerby in the Pictou Landing First Nations area. How can Northern Pulp claim to monitor their systems when a pipe rupture was undetected on land, let alone if the pipe was buried in the sea floor. I feel as though this risk needs to be better assessed because the potential for effluent to leak throughout the pipeline is very high. This applies for both the sections, land and ocean. This can pose problems for the fisheries and the marine ecosystem in the marine environment, but just as big a problem on land as the pipe is running right through the town of Pictou's water shed. I am sure the residents of Pictou do not want any effluent in their drinking water. Risking these aspects seem to be a very great risk that Northern Pulp is willing to take. I feel as though if the effluent leaking and entering the environment is seen as a problem, why is the idea of pumping it into the Northumberland Strait seen as an acceptable means of disposing of effluent in the first place?

Finally, this entire process, with the timelines put forth in the entire process, is once big farce. Northern pulp has had 5 years, to put together this large report on the entire project. That's fine. Where I draw the problem is that we as a concerned public, have only a fraction of that time, to formulate any concerns and put them forth to the government. In fact, the time line for concerns is only 30 days. This to me is a gross miscalculation. It is a hardly fair that the public has so little time to critique and raise concerns on a project that could potentially have a lasting and detrimental impact on the entire Northumberland Strait region, including that in neighboring provinces of New Brunswick and Prince Edward Island. This raises an aside to my main point. That being that why is the Government of Nova Scotia the one to make the decision when the Northumberland Strait is a body of water the impacts three separate provinces. As a fisherman, everything I do is monitored and controlled by the federally department of fisheries and oceans. They control everything in the fishery, as a federal body. So why does this decision that has the potential to impact everything mentioned above, being made by a provincial government? This does not seem right. Especially when you take into consideration that the Government of Nova Scotia has funded the planning and design of this project, and as well has helped the Pulp Mill with monetary funding and aiding them over the years with extended boat harbor leases or example, so that they can continue their environmental racism uninterrupted. All this seems to lead to the conclusion the that Government of Nova Scotia is unable to make this decision with a clear and concise conscience and therefore should defer and have the choice put into the hands of the Federal Government so that a more thorough investigation and assessment can take place so that everything is out in the open and there will be no more secrets and fear in the community. Because right now there is fear and division. And all this could be fixed by the Government if they aid on the side of caution, and don't give into the Mill once again. Don't let them have their way anymore. This project should be a Federal issue. No more romance between Northern Pulp and the Provincial Government.

Restating the three reasons that I oppose this project,

1) Lack of sufficient research regarding the Fisheries
2) Lack of monitoring and potential disastrous leaks
3) An underhanded process that only helps Northern Pulp and the overlooking of the Nova Scotian Government that this is a Federal issue

These points are a handful of reasons that I believe this project should be handed over to the Federal Environment Minister. This entire project should be subject to extreme scrutiny and not be taken lightly. A decision that impacts three separate provinces and millions of people should have to be approved by simply a few days' worth of thinking and processing. I plead that the Federal Government be involved, and the that the Northumberland Strait be taken care of and not be put at risk.

Thank you

Attached is my response to the above EA

March 9, 2019
To: NS Department of Environment
Re: Northern Pulp Environmental Assessment
Attn: Hon. Margaret Miller
Dear Minister Miller,

I am writing in response to Northern Pulp's proposed Replacement Effluent Treatment Facility Project.
I have been a resident of the Town of Pictou I am retired from a career working in Recreation, Health Promotion, Tourism and Community Development at the municipal (Town of Pictou) and provincial (Government of NS) and the Northwest Territories in both Iqaluit and Yellowknife.
Throughout my career I have been dedicated to promoting and protecting natural spaces and parks for the enjoyment of citizens and for the sustainability of the environment for future generations. On a personal level I have been involved in the construction of trails in NS and I am an avid outdoor enthusiast specifically hiking and kayaking.
Whether it be in my career or personal life I have experienced numerous negative impacts as a result of the Northern Pulp operation at Abercrombie Point. To name a few:

- Decreased visitor numbers and cancellations of bookings by customers to our tourism sites/attractions/special events as a result of the putrid odour and smog coming from the mill.

- The inability to enjoy our own property and outdoors in general in the Town of Pictou and surrounding area again as a circumstance of the stench and smog emanating from the mill.

- Personal danger and harm; my wife and I had an experience kayaking at the mouth of Pictou Harbour when we had to put our kayaks ashore due to the blinding effect of the smog and the level of the toxicity burning our eyes. Not the type of experience anyone would expect when experiencing Canada's Ocean Playground.

The proposed effluent treatment facility does not rectify these concerns and in fact only serves to compound them and add additional threats to our environment and personal health. I am specifically concerned about the following:

A. Town of Pictou Watershed

As a citizen of the Town of Pictou I have long awaited improvement to the water quality in our community. A new water treatment facility was put into operation in 2018. The proposed route for effluent pipe is through and in proximity of the Towns protected watershed area. The Mill has had numerous breaks in the pipeline line which currently dumps the effluent into Boat Harbour. There is no confidence that Northern Pulp can prevent future spills nor put into place sufficient monitoring to detect spills and take action quick enough to prevent poisoning of the Town's water supply. Typically, past behaviour is an accurate indicator of future behaviour, that has certainly been the case with Northern Pulp and I suggest that this risk is not acceptable given their past record of spills. I should also note that the Town Water Shed feeds private well systems of residents living in the Municipality of Pictou County. A pipe carrying toxic waste through a watershed area is not acceptable.

B. Air Quality

Northern Pulp proposes to burn the sludge captured the newly prosed treatment process in their boilers. The levels of toxicity and odour will be worse.
I am not sure what the appropriate word is, perhaps "ironic", better yet "absurd" that the Town of Pictou has a Fireplace By-law passed in 2012 which in part deals with levels of smoke deemed to be acceptable, or not. An exerpt from the by-law is included below:
TOWN OF PICTOU
OUTDOOR FIRE BY-LAW
BE IT RESOLVED that this By-law, known as the Outdoor Fire By-law for the Town of Pictou be enacted effective this 30th day of May, 2012;
j. "Nuisance" means the causing of any smoke or other emission from any fire permitted or allowed under this By-law, or otherwise, that adversely affects the reasonable enjoyment by other persons of their property;

Surely, if this basic standard was applied to the fire, in this case, smoke from Northern Pulp stacks it would be classified a nuisance and shut down. The current standards for air quality in my opinion as a person who lives in this are is not acceptable. It is not fair or reasonable to expect any person, by any standard, to endure this poor air quality. Imagine this level of toxicity, smog and stench in any other jurisdiction in NS. For example, on the Halifax waterfront, it would not be acceptable there and Pictou residents and visitors should not be expected to endure it any longer.
The Town of Pictou uses the Ringelmann Visual Chart to assess compliance to the by-law and fines can be levied if smoke is rated at Ringelmann level 1 or 20% opacity which smoke emitted from Northern Pulp does not meet frequently on days of high humidity in our community, thereby removing our ability to enjoy the most basic air quality standards. The accompanying odour on these days is by any reasonable standard unbearable and not in sync with today's norms, especially in an era when most workplaces and communities are enforcing, for example, no scent policies and programs.

3. No Public Confidence

The public is again being asked to believe the science and engineering for the new treatment facility. In their matrix table " E.1.1-1 Summary of Significance of Project related Residual Environmental Effects " the mill claims that there is absolutely No Significant expected impact on all of the environmental areas they are required to address. The public has no confidence in this corporate claim especially based on past history of effluent pipe spills, non-compliance to air quality standards and the like.

4. Dredging and Federal Regulations

On page 56 of the EA document Northern Pulp makes a very cursory reference to necessary approvals for the dredging required to put the pipe in the Northumberland Strait. It is not satisfactory that Northern Pulp be considered for EA approval at a provincial level when they have not submitted their dredging plan for approval for by the Federal Government. There are a number of Federal regulations which impact on dredging permits including but not restricted to: Fisheries Act, Navigation Protection Act, and the Canadian Environment Assessment Act. Northern Pulp should be required to pass these approvals for dredging prior to consideration for approval by the NS Dept. of Environment. In particular, as in the case with dredging in the St. Lawrence Seaway which was subject to the aforementioned Federal Regulations, Northern Pulp has no way of ensuring that toxins, contaminants present from past industrial activities in the Ferry Terminal area at Caribou would not be disturbed as a result of the pipe installation.

In conclusion I ask the Minister to reject Northern Pulp's request for EA approval for a number of reasons as stated above as well as the following:

- The time permitted to review their 1700 page application is not fair.
- Northern Pulp made changes to the proposed pipe route and did not hold additional public consultations to present the rationale for this change and to seek input from the public and stakeholder groups.
- They make a number of claims throughout the report where "they don't expect" any harm to be done. This is does not demonstrate confidence in their own ability to implement a safe and reliable project.
- Northern Pulp should be required to submit to a more thorough environmental assessment through the Canadian Environmental Assessment Agency due to the complex nature of their proposal, anticipated harm to the environment, the local economy, and quality of life of residents who live in proximity to the mill.
- It does not make sense that regardless of the treatment process proposed that we would put the same substance that has gone into Boat Harbour and that will cost at least 200 million dollars to mitigate, into another body of water.

Respectfully submitted,

Hello,

Attached is a letter from My Grandfather regarding Northern Pulp.

Thank you

Dear Minister Miller,

I am writing to you regarding Northern Pulps Replacement Effluent Treatment Facility Project.

My name is . I live in Toney River, Nova Scotia. I have been a commercial fisherman in the Pictou area for 40 years now, and have both my sons employed in the fishery, one of whom is a captain, and the other that I employ. I also have a grandson employed in the Fisheries. So, to say that the Northumberland Strait and the local fishing industries is not gravely important to my family would be a substantial understatement. Fishing has been a way of life in our family for many years, since before I was born, and will continue well into the future, so long as we protect the Northumberland Strait and all the resources that live in it. This is why I write to you today, to demonstrate my objection and involvement with the project. I want to express concern for my children, their children and my family's future well being and wish to make sure that they are taken care of ad their way of life is not jeopardized in the future.

I wish to raise three points of concern with the project.

First, as a fisherman I am concerned, that the proposed effluent pipe will be a detriment to the local fisheries, including that of lobster, rock crab and herring. The proposed outfall location is premium breeding grounds for all of these fisheries, and are of grave importance to the local area, as well as the entire economy of Nova Scotia. I feel as though there should be a greater deal of importance placed on protecting these fisheries. The science provided in Northern Pulps proposal is outdated, being conducted in the 1960's. Our industry is under constant pressure to evolve and become more sustainable and improve our fishing methods as well as our conservancy methods. How can a large corporation, who is not even Canadian owned, come in and attempt to infiltrate our waters, and not be subject to more severe outside pressures to ensure that what they are doing is not only scientifically acceptable but also morally right. Just because they claim that the effluent technically passes whatever loose requirements imposed by the5555, does not mean that is morally right to be pumping anything into the ocean. All levels of government have been claiming that we need to protect the ocean, that we need to cut down on pollution and begin to care for our environment because we won't have it forever. How can someone say this but then consider pumping effluent full of toxins into the ocean. The Government can't have it both ways and are going to have to step up to the plate. Is big industry more important than the health and well being on not only the Environment and ecosystem of the Northumberland Strait, but as well as the health and well being of the people that live there. Nova Scotia is considered Canada's ocean playground, and that's for good reason, the province is surround by the ocean. But what happens if Northern Pulp wants to start pumping their effluent into that playground? No ones going to want to play there anymore.

A separate point I would like to bring up is the monitoring of the pipe and its wellbeing. My main point being that how will the pipe be monitored? They claim that the accidental release of effluent can occur. There is an example of this in the fall of 2018 when a ruptured pipe was

discovered by a passerby in the Pictou Landing First Nations area. How can Northern Pulp claim to monitor their systems when a pipe rupture was undetected on land, let alone if the pipe was buried in the sea floor. I feel as though this risk needs to be better assessed because the potential for effluent to leak throughout the pipeline is very high. This applies for both the sections, land and ocean. This can pose problems for the fisheries and the marine ecosystem in the marine environment, but just as big a problem on land as the pipe is running right through the town of Pictou's water shed. I am sure the residents of Pictou do not want any effluent in their drinking water. Risking these aspects seem to be a very great risk that Northern Pulp is willing to take. I feel as though if the effluent leaking and entering the environment is seen as a problem, why is the idea of pumping it into the Northumberland Strait seen as an acceptable means of disposing of effluent in the first place?

Finally, this entire process, with the timelines put forth in the entire process, is once big farce. Northern pulp has had 5 years, to put together this large report on the entire project. That's fine. Where I draw the problem is that we as a concerned public, have only a fraction of that time, to formulate any concerns and put them forth to the government. In fact, the time line for concerns is only 30 days. This to me is a gross miscalculation. It is a hardly fair that the public has so little time to critique and raise concerns on a project that could potentially have a lasting and detrimental impact on the entire Northumberland Strait region, including that in neighboring provinces of New Brunswick and Prince Edward Island. This raises an aside to my main point. That being that why is the Government of Nova Scotia the one to make the decision when the Northumberland Strait is a body of water the impacts three separate provinces. As a fisherman, everything I do is monitored and controlled by the federally department of fisheries and oceans. They control everything in the fishery, as a federal body. So why does this decision that has the potential to impact everything mentioned above, being made by a provincial government? This does not seem right. Especially when you take into consideration that the Government of Nova Scotia has funded the planning and design of this project, and as well has helped the Pulp Mill with monetary funding and aiding them over the years with extended boat harbor leases or example, so that they can continue their environmental racism uninterrupted. All this seems to lead to the conclusion the that Government of Nova Scotia is unable to make this decision with a clear and concise conscience and therefore should defer and have the choice put into the hands of the Federal Government so that a more thorough investigation and assessment can take place so that everything is out in the open and there will be no more secrets and fear in the community. Because right now there is fear and division. And all this could be fixed by the Government if they aid on the side of caution, and don't give into the Mill once again. Don't let them have their way anymore. This project should be a Federal issue. No more romance between Northern Pulp and the Provincial Government.

Restating the three reasons that I oppose this project,

1) Lack of sufficient research regarding the Fisheries
2) Lack of monitoring and potential disastrous leaks
3) An underhanded process that only helps Northern Pulp and the overlooking of the Nova Scotian Government that this is a Federal issue

These points are a handful of reasons that I believe this project should be handed over to the Federal Environment Minister. This entire project should be subject to extreme scrutiny and not be taken lightly. A decision that impacts three separate provinces and millions of people should have to be approved by simply a few days' worth of thinking and processing. I plead that the Federal Government be involved, and the that the Northumberland Strait be taken care of and not be put at risk.

Thank you

From:
To: Environment Assessment Web Account
Subject: Northern Pulp ETF Project Concern
Date: March 9, 2019 12:46:55 PM

Dear Honourable Minister Miller:

I am writing in response to Northern Pulp's environmental assessment for their new effluent treatment facility that would discharge up to 85 million litres daily of treated pulp effluent daily and into the Northumberland Strait.

Our family has had cottages on Moodie Cove since the early 1900's, long before the mill compromised air quality and before its effluent hugged the shoreline along Lighthouse Beach. My deep appreciation for the Northumberland Strait's beauty and clear water is what keeps our family coming back.

As a police officer with 30 years of experience, the history of Northern Pulp's parent companies is of particular concern to me. Northern Pulp is owned by Paper Excellence a subsidiary of Indonesian conglomerate, Sinar Mas. Sinar Mas is owned by the Widjaya family, one of the wealthiest families in Indonesia. Their businesses are responsible for deforestation of the Indonesian rainforest; contributing to hazardous level of smog in Singapore and Malaysia; defaulting on a $14 billion loan; greenwashing their companies; and bribing government officials.

As Northern Pulp wraps up 50 years of deceit and environmental racism with Pictou Landing First Nation, they say they are ready to start a new and improved environmental legacy in Nova Scotia. Sinar Mas does not have their own country's best interests at heart. How are we to believe that their environmental practices in Nova Scotia will ever be any better. Below are a number of examples of questionable practices and concerns by Sinar Mas, parent company of Northern Pulp.

1. Asia Pulp and Paper makes Corporate Criminal List top 10

https://globalexchange.org/2018/11/23/ten-top-corporate-criminals-of-2018

In 2018 Asia Pulp and Paper was listed in the top ten of corporate offenders on the Global Exchange list. Global exchange is an international human rights organization dedicated to promoting social, economic and environmental justice around the world. Each year it releases its top corporate criminal list too highlight some of the world's corporate worst-of-the-worst on issues like violations of human rights and workers' rights, environmental destruction, war profiteering, and tax evasion and other white-collar corporate crime, just to name a few.

Asia Pulp and Paper made Global Exchange's 2018 "10 Top Corporate Criminal" list for continued destruction of the Indonesian rainforest and peatlands and attempting to "greenwash" its image for the global market

2. Executives with Sinar Mas arrested in Bribery scandal in Indonesia

An October 2018 article in Mongabay (detahttps://news.mongabay.com/2018/10/palm-oil-executives-arrested-in-bribery-scandal-in-indonesia/ils the arrest) details the arrest of three Sinar Mas executives *after an employee was caught bribing politicians to kill an inquiry into water pollution and plantation licenses in Borneo*. Two of the executives were employed with a palm oil company which falls under Sinar Mas and according to the Mongabay article was located *near Lake Sembuluh in Seruyan district, in the Bornean province of Central Kalimantan. The lake is ringed by oil palm plantations and mills and has become severely polluted, with residents complaining of itchy skin after swimming in its waters and the collapse of fish stocks.*

PT Binasawit Abadi Pratama, was a smaller company the executives worked for operating near the lake.

A tip was received by investigators about *a planned meeting in Jakarta between Binasawit representatives and provincial legislators, during which the bribery was supposed to take place.* Further investigation revealed that there were problems with Binasawit permits and that *Sinar Mas wanted to pay off the legislators not only to kill the inquiry into water pollution but also to tell the media that Binasawit's permits were in order.* At the conclusion of the investigation two executives from Sinar Mas were charged.

3. Greenpeace Slams AP&P over links to Deforestation

https://www.greenpeace.org/usa/news/greenpeace-slams-app-sinar-mas-links-deforestation-ends-engagement-company/

An article by Greenpeace International in May of 2018 calls out Asia Pulp and Paper (AP&P) over its deforestation practices in Asia and indicated that Greenpeace has ended all engagement with the company. Through *mapping analysis by Greenpeace International* it has been revealed that *almost 8,000 ha of forest and peatland has been cleared since 2013 in two concessions which are, through ownership, linked to APP and its parent company the Sinar Mas Group.* Greenpeace has put *these allegations to APP/Sinar Mas. The group failed to provide a credible response or to take meaningful action. As a result, Greenpeace has ended all further engagement with APP/Sinar Mas.*

In 2013 APP had adopted a Forestry Conservation Policy (FCP) and had *committed to end forest clearance within its own and suppliers' concessions, protect remaining forests in these areas, improve management of peatland and work with communities to resolve social conflicts.* Greenpeace had been advising and inputting into the FCP, however when it was able to show the deforestation of nearly 8000 hectares through satellite imagery and company deeds, it ended its relationship with APP stating that *this new evidence tells us that APP/Sinar Mas is not genuinely serious about stopping deforestation in Indonesia.* Greenpeace further called upon customers of APP to demand they end their deforestation practices and that if *APP and the Sinar Mas Group do not immediately comply, then all customers should cancel contracts and walk away.*

4. Behind-the-scenes ties and significant influence over wood suppliers linked to fires and deforestation in Indonesia.

https://www.seattletimes.com/business/ap-exclusive-pulp-giants-makeover-obscures-supplier-ties/

According to an AP exclusive published in the Seattle Times, December 19, 2017, Sinar Mas, known by its international trade name, Asia Pulp and Paper, one of the world's largest paper producers was attempting to "Greenwash" its image for the global market. In the article it states that Asia Pulp and Paper (APP) *has insisted in company publications, public events and to the media that most of the companies that supply it with wood are "independent," not owned by it or in other ways affiliated with it.* The AP reviewed over 1000 pages of company records and determined that 10 individuals owned these "independent' wood suppliers, and *that six are employees of the Sinar Mas group and two are former employees, one with links to the Widjaja family, which owns Sinar Mas. Several work in the finance department of Sinar Mas Forestry.* According to the article, Sinar Mas had pledged in 2013 to stop deforestation however the investigation found that *a company owned by two employees of Sinar Mas Forestry has been cutting down tropical forest on the island of Borneo since 2014.*

The AP was able to find that 27 so called independent wood suppliers had links to Sinar Mas even though the company had told the outside world that they were independent. They were able to identify some by *matching biographical details in the documents, including birth dates, to information in social media profiles, news reports, forestry industry documents and other sources.*

The article goes on to describe that on top of its pledge to stop deforestation in 2013, that Siiar Mas made another *pledge to gain prior and informed consent of local communities for new plantations,* but in spite of this, *Sinar Mas is pressing ahead with plans to turn 66,000 hectares (163,000 acres) of state land in the Bangka Belitung island chain off Sumatra into industrial forestry plantations despite substantial opposition from locals. The move puts the company on a collision course with villages that farm on the land and*

which some 100,000 people call home.

5. Defaulted on $14 billion worth of bonds and loans in 2001

In the mid-1990s Asia Pulp and Paper (APP) embarked on an aggressive expansion strategy to turn their pulp and paper operations into a global player. Billions of dollars were required to fund the intended expansion. According to the Bulls and Bears Blog, t*he company commenced a global drive for funds and managed to issue* billions *of dollars' worth of bonds starting 1994, with the help of the eager Wall Street investment banks, and a story that sold with investors: an emerging market blue-chip, with competitive advantage in fast-growing Indonesian hardwood, and operating in low-cost Indonesia while collecting revenue in dependable US currency.* (http://stocktaleslot.blogspot.com/2005/11/asia-pulp-paper-debt-default.html.

Several years later, after a down turn in global paper prices , APP were unable to meet their debt payments on bonds , loans and trade payables and according to Wikipedia, *in 2001, Asia Pulp & Paper (APP), the subsidiary of Sinar Mas Group, called a standstill on $14 billion worth of bonds and loans and stopped repaying its debt, including interest payments, in what is still the largest default to foreign investors in Asian market history.* This included *about US$6.7 billion of dollar notes, the biggest missed bond obligation by an Asian company to date,* (The Strait Times, Published Apr 28, 2015, https://www.straitstimes.com/business/worst-asian-default-forgiven-as-indonesia-billionaire-sells-debt).

The consequences for the Widjaya family were limited and as the ultimate owners of APP*, there was no forced pledging of their personal assets, nor any injection of assets to prop up the company for debt restructuring. The family and their associates were still left as the operational managers after the whole debacle. (Bulls and Bears Blog)*. The Widjaya family was also the owner of Bank Internasional Indonesia, *before it was taken over and bailed out by the government in 2001 because it was unable to force Sinar Mas and other borrowers to repay their debts,* and that, *more than half of the bank's loans were made to Sinar Mas companies, violating rules on inter-group lending.* (Bloomburg Billionaire Index, Overview Eka Widjaya)

The Widjaya family business went on to recover from this debt default and expanded their properties in Indonesia, Singapore and China and according to the Bloomburg Billionaires Idex , Eka Widjaya , the founder of the family business was listed in 2017 with a net worth of $ 8.1 Billion.

Minister Miller, our natural resources deserve better than Sinar Mas. Nova Scotia deserves better. Pictou County deserves better. I am asking you to reject Northern Pulp's EA proposal. Their EA does not prove that their project will not cause adverse effects to the environment, and given their parent company's history of deceit and environmental destruction, there is no evidence to show that Northern Pulp has any intention of starting an improved environmental legacy here in Nova Scotia.

Sincerely,

From:
To: Environment Assessment Web Account
Subject: Northern Pulp Effluent Treatment Facility Project Concern
Date: March 9, 2019 1:03:39 PM

Dear Honourable Minister Miller:

I am writing in response to Northern Pulp's environmental assessment for their new effluent treatment facility that would discharge upwards of 85 million litres of treated pulp effluent daily into the delicate ecosystem of the Northumberland Strait.

My husband and I have a cottage on Moodie Cove, Pictou Landing. As recreational water enthusiasts, we have spent our summers exploring the Strait and observing its diverse marine life. The Caribou Harbour area is one of our favourite areas to explore. We travel from the Pictou Landing Marina, make our way around the PEI Ferry markers and anchor off Munroe's Island. Here we will walk the beaches, swim and snorkel. While snorkelling, we have noticed the Caribou area is rich in marine life and is home to large populations of juvenile fish and crustaceans.

Concern: Northern Pulp's Community Liaison Committee - Lack of Transparency

While there are countless data gaps and inaccuracies in Northern Pulp's Environmental Assessment related to potential harmful environmental effects of the Project, I would like to focus on one concern with respect to public consultation, specifically Northern Pulp's Community Liaison Committee.

Northern Pulp provides the following description of their Community Liaison Committee (CLC) in their EA.

"NPNS has an existing Community Liaison Committee (CLC). The CLC serves as a formal consultation process with certain local stakeholders in compliance with NPNS' Industrial Approval to operate. The CLC serves a very important role in providing advice and facilitating two-way communication. The CLC members represent themselves as members of their community and provide their own personal perspective to the committee. They also provide constructive input on how the company may better address and respond to the community needs and concerns. The CLC meets at a minimum twice annually, in Spring and Fall, as well as convening on an as-needed basis. The CLC includes representatives from Pictou Landing First Nation, the communities of Abercrombie, Pictou Landing Moodie Cove and Pictou, NPNS staff, and NPNS executives."

In the Socio-Economic Impact section of the NPEA, under *8.14.6 Follow-up and Monitoring [operation and maintenance phase]*, Northern Pulp states: *The existing Community Liaison Committee will continue to serve the very important role in providing advice and facilitating two-way communication between the local*

community and NPNS.

And also under the Socio-Economic section, under 8.15.3.3 Characterization of Residual Environmental Effects, the NPEA states: *The existing CLC will continue to provide two-way communication between NPNS and the surrounding communities.*

Northern Pulp's CLC meeting minutes (sample: http://northernpulp.ca/assets/Uploads/NPNS-CLC-June-2018-summary-notes-FW.pdf)) indicate there is a representative from Moodie Cove on the CLC, however no name is provided for that committee member nor any of the other committee members.

As mentioned above, our cottage is on Moodie Cove, along with 20 other cottages that are accessed by three private roads. There are no permanent residents on Moodie Cove. . I contacted an executive member of the association for our road, , to ask if he knew who the representative was for Moodie Cove on Northern Pulp's CLC. was unaware there was a representative and called Northern Pulp on behalf of our association to find an answer.

received a call back from Northern Pulp's Technical Manager. indicated that the CLC members are anonymous and that if we wanted to present any of our views or questions to the committee, it would have to be through her.

In Nova Scotia Environment's *Guide for the Formation and Operation of a Community Liaison Committee (*https://novascotia.ca/nse/issues/docs/Community_Liaison_Committee_Guideline.pdf*)*, it states the purpose of a CLC is: *To represent community interest by providing an avenue for the mutual exchange of information between the proponent and the community with respect to any existing or potential environmental effects of the project plan and activities.*

The Guide also details the following mandate and responsibilities by the proponent and CLC members:

Section	Description	Issue/Concern
The mandate	*A forum whereby the residents can bring any issues of public*	The only residents who can bring their issues forward, are the ones sitting on the CLC, therefore Northern Pulp's CLC fails to represent the concerns of their communities.

	concern related to proponent's activities to the attention of the facility operators.	
Proponents Responsibility	*Notice of the CLC formation and members must be made known to the residents of the affected area by the proponent."*	Northern Pulp's members have remained confidential making it impossible for residents to bring their concerns forward to the CLC.
Proponents Responsibility	*The proponent should ensure that the views of the CLC are made available to the public in an appropriate manner.*	Minutes from CLC meetings made available to the public are vague and provide no detail on input from CLC members (sample: http://northernpulp.ca/assets/Uploads/NPNS-CLC-June-2018-summary-notes-FW.pdf)
CLC Members' Responsibility	D*iscussing community views, issues and concerns with respect to the project plan and activities.*	It is impossible for CLC members to adequately express the views of the community when the community is unaware of who to express their views to (CLC members).

In summary, Northern Pulp's Community Liaison Committee fails to facilitate any genuine or meaningful two-way communication between the local community and Northern Pulp. The CLC also fails to effectively represent the concerns and opinions of the surrounding community. It is my understanding that Northern Pulp's CLC structure has been brought to the attention of Nova Scotia Environment in the past,

and that NSE has accepted this poor level of functioning.

Not only did Northern Pulp fail to hold a second set of public consultation sessions to inform the community on changes to their proposed ETF and the new Caribou outfall location, but they are now suggesting their CLC committee will be a primary tool in mitigating environmental effects from the construction and operation of this new facility to the socio-economic environment. (section 8.14 - Socio-economics Environment, 8.14.4.2 - Mitigation).

As the Minister of Environment, you are obligated to *'consider steps taken by the proponent to address environmental concerns expressed by the public'* when making your decision. Northern Pulp has not done an adequate job informing the public and collecting concerns, and therefore cannot properly address them. As well, Northern Pulp does not have the proper infrastructure in place to address any public concerns during the construction and operation phases of the project.

Based on the above outlined concerns, combined with the extensive data gaps in the NPEA, I am requesting that you reject Northern Pulp's proposal. Northern Pulp has failed to demonstrate that their project will not cause adverse effects to the environment that can be mitigated.

Sincerely,

From:

Subject: Comment on Northern Pulp pipeline plan
Date: March 9, 2019 1:19:01 PM

Hi folks,

My name is and I work at the Ecology Action Centre I grew up in Pictou County, and know the waterways of the Northumberland Strait, in particular Merigomish Harbour, very well.

Thanks for the opportunity to provide feedback on the Northern Pulp effluent treatment plant and pipeline proposal.

As a kid, I remember walking across the Pictou causeway with my parents, holding a sign protesting the use of Boat Harbour as an effluent dumping ground. My father, , was Citizens Against Pollution, a community group formed to raise awareness of the negative health effects of the pulp mill on the residents of Pictou County.

This effluent treatment plan is a bad idea. A pipeline into the Northumberland Strait will negatively affect the livelihoods of fisherfolk and Indigenous communities moreso than any other group of people, and for that reason alone it should be abandoned.

However, there are many other reasons the pipeline plan should be aborted, including:

- The plan will increase the scale of the environmental damage from one county in Nova Scotia to to the waterways of all three Maritime provinces.

- The track record of Northern Pulp shows that a leak or some failure of the effluent treatment infrastructure is more than likely, and that such a failure could go unnoticed for too long.

- The legacy of disrespect and abuse of the Pictou Landing First Nation will be continued if this pipeline is installed.

- That the government of Nova Scotia acts as both the regulator and the funder of the treatment facility shows that they are not in a position to make clear-headed decisions about it. A federal Environmental Assessment is entirely appropriate here.

The pulp mill in Abercrombie is old and out of date, and it will eventually close. As the government of Nova Scotia, you have the opportunity to prepare for that inevitability by retraining workers and increasing environmental standards so that the forestry and the fishing industries can cooperate.

Or, you can continue to throw good money after bad, shifting the burden of cleaning up the Northumberland Strait, rebuilding the economy of the Town of Pictou, and repairing the relationship with the Pictou Landing First Nation onto the next generation, all while degrading a special part of the world in the process.

30 years from now, will my children still be speaking truth to power on this issue?

Please choose wisely.

Sincerely,

Subject: Replacement Effluent Treatment Facility Project comments
Date: March 9, 2019 1:29:16 PM
Attachments: Northern Pulp Environmental Assessment Comments.pdf

---

Good afternoon,

Please find attached my comments on the proposed Replacement Effluent Treatment Facility Project submitted by Northern Pulp.

If you have any questions or comments for me, please do not hesitate to get in touch by email at @unb.ca, or by phone

Sincerely,

March 7, 2019

To whom it may concern at the Environmental Assessment Branch of Nova Scotia Environment,

I write you today to voice my concerns over the replacement effluent treatment plan proposed by Northern Pulp. While I moved to New Brunswick last summer, I was born and raised in Nova Scotia, and have been an active member of the angling community along the rivers and saltwater that flow from the Northumberland Strait . I have also been a member of the Atlantic Salmon Federation For the danger posed to Atlantic salmon and other vulnerable species, I ask you to delay any decision about this proposal until there has been adequate time for risk assessment and public consultation.

As I am sure you are aware, Atlantic salmon are listed as a species at risk by COSEWIC. The population of Atlantic salmon in North America has been in steady decline for decades. Since 1995, the population of one sea-winter (1SW) salmon has fallen by about 56% as compared to the population measured between 1971 and 1985[1]. As is referenced by Northern Pulp on p.379 of their proposal, two of the most critical influences in the decline of Atlantic salmon are climate change, and changes to ecosystems and habitat. Atlantic salmon are very sensitive to changes in temperature[2] and water quality. The proposal lists potential operational effects on marine fish species on p.385. The list includes the change in temperature as a result of effluent discharge, but does not elaborate on the extent of the effects this could have on Atlantic salmon or any other species for that matter. Furthermore, there are no mitigation measures listed for this temperature increase. On p.389, they say that the temperature of the water will be within 0.1 degree Celsius of the background temperature at the end of the 100m mixing zone. I find it challenging to believe that a continuous discharge of 62 to 90 million litres of effluent daily would not have a more profound effect on the temperature of a much larger area in the Northumberland Strait over the the course of several decades (Northern Pulp has been vague about the potential lifespan of this project once complete in their Project Schedule on p.81). Organizations like the Margaree Salmon Association, the Atlantic Salmon Federation, and the Miramichi Salmon Association have invested a substantial amount of time and money into conservation efforts for the shared goal of protecting this vulnerable species. Additionally, the angling industry for Atlantic salmon in Atlantic Canada is a driver of local economies and tourism dollars, with $166 million in spending on the industry in 2010[3]. Based on the changes to the habitat and water quality for Atlantic Salmon that would result from the proposed project, I think it is inevitable that the species would suffer. To damage this resource is conservationally

and financially counterintuitive. Due to this potential for harm, I ask that you delay your decision on the matter until a complete risk assessment to the species can be completed.

While the issue of conservation of Atlantic salmon is one that is very important to myself and several others personally, my points above only address the potential concerns for this one species. There are countless other species that will certainly be impacted should this project be allowed to proceed. The health of many of these other species is depended on by local commercial fishermen for their livelihoods. I urge you to consider the magnitude of the impact on fish habitat and health before allowing this project to continue.

Sincerely,

Dear Sir or Madam:

RE: Northern Pulp's Replacement Effluent Treatment Facility Project

I am a commercial fisher and a resident of Pictou County. I grew up in Caribou very near the Caribou ferry terminal. My father and many other family members were commercial fishers in Caribou. I fished in the industry since the 1970's, starting when . Following attendance at university, I was drawn back home by the Northumberland Strait. I have owned my own fishing enterprise I fish rock crab, herring and scallops out of Caribou. I fish lobster in another area. I have a large financial investment in the fishing industry. The health of the Northumberland Strait is vital to my retirement and my future. My son has recently started fishing with me and a clean and sustainable Northumberland Strait is essential for him to have a future in the fishing industry.

As fishers, we invest a lot of time, energy and money to maintain the sustainability of the fishing industry. We regulate ourselves by proposing and agreeing to such things as catch limits, buffer zones, reduced efforts, and modified nets and traps. The EA proposal will harm the Northumberland Strait, our fishery, and our future.

There are many errors and missing information in the proposal, as follows:

1. The proposal did not consider the behaviour of herring. Herring gather in the deep waters of the ferry channel and other deep water areas to get away from predators. They come out of the deep waters at night to spawn on the shallow banks in the adjacent areas. If fresh, hot water containing who knows what is pumped into their deep water hiding zone, the herring will not go there and will have no where to hide. I believe this will have irreversible effects on the herring species in the area, and their spawn.

2. Tuna are in the area of the outfall. While fishing herring last year, I saw approximately 6 tuna charter vessels at one time in the area outside Caribou Harbour. Last year, tuna washed ashore in

Caribou Island and Simpsons Beach (part of Caribou - Munros Island provincial park).

3. Contrary to what is showing in Figure 8.12-3 of the proposal, rock crab is fished all over the proposed effected area. The rock crab fishing area we call "Africa" because of its shape, runs from Caribou Island, Pictou Island to about Arisaig. The footprint of the pipe runs through a vital rock crab nursery where juvenile crab are spawned and grow to maturity.

4. As fishers, we are required to maintain a log book while fishing rock crab, herring, scallops and lobster. Although we fish these species in a very large area throughout a day of fishing, we are required to record our fishing location just once per day. As such, our logs do not accurately reflect the expansive areas where we fish. For example, in one day, a fisher may leave Caribou Harbour and travel to Charlottetown Harbour and fish everywhere in between. In the fishery log, if a fisher records fishing in Charlottetown Harbour, the fishing effort in all other areas is not reflected.

5. Fishing of some sort is conducted everywhere in the Northumberland Strait. It is fair to say there is no area of the strait that is not fished. Fishing areas for a certain species may vary from year to year. Therefore, using data of fishing areas from 2001, for example, as was used in the proposal, may not accurately reflect the fishing area in 2018 for that same species. Fish move and follow food sources. Piping of effluent will be detrimental to phytoplankton and zooplankton which are the food source for fish and mammals and are building blocks for all ocean creatures.

6. Some fishing bottoms also may change over time, or from year to year, due to storms or man made causes. I have fished lobster in Wallace since 1993. The construction of the fixed link between New Brunswick and Prince Edward Island took place between 1993 and 1997. The building of the fixed link brought great changes to the lobster fishery in my area - huge decline in lobster catches and changes to the sea floor. I witnessed a change in the water which went from clear to very muddy everyday. I lost a large area of my fishing bottom due to sedimentation. What was once a rocky floor was covered by mud or silt. When I pulled my lobster traps, they were covered with a fine muddy film. The film also covered the bait on my traps which hindered their ability to attract lobster, caused the bait to rot, and attracted sand fleas which ate the bait. I suspect that the silt interfered with the lobster's respiratory and other functions as they were covered with the muddy film as well.

The lobster fishery in that area is only very recently starting to recover. I notice less silt in my traps and the water is becoming clearer. Things are going back to where they were when I first bought my lobster licence in 1993 before the start of the fixed link construction. My catches are finally returning to what they were before the construction. The value of fishing enterprises was greatly reduced in this area for the last 20 years or so, and they are now just recovering to be on par with fishing areas not effected by the fixed link. I did not receive any compensation for my economic loss or the damage to the environment. I don't want that to happen again.

7. The scallop information in Figure 8.12-5 is not accurate. In the scallop logs fishers must complete, there is no place to enter fishing location for every area where scallops are fished. There is no way to determine where scallops are caught in the strait. This figure also shows

scallop catches in areas where there is a buffer zone and therefore no scallop fishing in that area. This proves that the figure is not accurate and should not be relied on. It should also be noted that recreational scallop divers dive for scallops in the area behind Munros Island, and in the area around the outfall location. They are permitted to dive for scallops within the 1 mile buffer zone, but they don't keep logs or report where they have fished.

8. Figure 8.12-6 is also not accurate. The map does not show the herring nursery which is in the area of the outfall. Also, there is herring fishing all around Pictou Island and not just as indicated. We also fish for herring in the area of the proposed outfall location. Herring is a fixed gear fishery. We use anchors on each end of our herring nets. The pipe and proposed no anchor zone will significantly interfere with our herring fishery. It is not possible for us to simply go somewhere else to fish if the fish are located in the area of the outfall or the no anchor zone and not anywhere else. The herring pack consists of a large group of boats all fishing for herring at once - possibly 200 boats in the same close area at one time. The pack is so large that sometimes the PEI ferry steers out of its normal route to avoid us.

9. Figure 8.12-8 is also not accurate. There are mackerel around Pictou Island and Caribou Island and in area of the outfall. There is mackerel in Caribou channel and Pictou channel, and around every wharf. There are many people who fish mackerel from all the wharves in the area, including Caribou. They also fish for bass, smelts, capelin and other fish from the wharves. This is an important healthy food source for many people in our area and part of our tradition and culture and must be protected.

Mackerel like going along the edge of the channel because it is deep, and they are hunting the bait fish which is also in the channel. They tend to swim back and forth from deep to shallow water.

10. The scallop buffer zone is not accurately depicted in Figure 8.12-10. The scallop buffer zone extends all around Munros Island and Caribou Island. The buffer zone is 1 mile from any point of land, which includes all islands.

11. It is not appropriate or accurate to use the characteristics of Pictou Harbour as a proxy for those of Caribou Harbour. Caribou Harbour is closed except for a narrow opening. It does not flush well. There is more flushing in Pictou Harbour and 3 large rivers flow into it. My father, who grew up in the area, used to tell stories of his grandparents walking cattle from Caribou Island to Munros Island (which in the past, was also known as Doctor's Island) at low tide. This shows how narrow and shallow that area is. The ferry channel is artificial and was created when the ferry services started, and is maintained only through periodic dredging.

12. The wharves at Caribou Harbour are used for more than tying up vessels. We sell our catches to the public and commercial buyers at the wharf. During herring season, for example, fish buyers set up buying stations where we off load our catches. Buyers who use the vacuum system to remove herring from the boats, pump water from the harbour onto the vessel in order to suck up the herring. It is like a wet vac.

During lobster season, the buyers tie large numbers of lobster in floats in Caribou Harbour until they are transported for processing. Floats are large containers which allow for water to flow in and out to keep the lobster alive. Will this water be contaminated by effluent thus making the fish toxic?

We use water from the strait to keep our catch alive during the day. I am concerned that I will inadvertently use effluent water on my fish which could cause contamination. How will I know the difference between water that contains toxic effluent and water that does not? I also use that water to wash my fishing boat and gear as I enter the channel at the end of my day. I don't want to use effluent to clean my boat and gear. What effect will this have on my heath and my equipment?

There is a lack of information provided in this proposal and large gaps in terms of the effect on the environment and ecosystem of the Northumberland Strait. Much of the information that is provided is not accurate and there are a lot of discrepancies. This makes me question the credibility of the entire proposal. The proposal must be rejected. Nova Scotia is supposed to be Canada's ocean playground. We don't want it to become Canada's ocean dump. Northern Pulp should give in, give up and get out.

Concerned fisher,

From:
To: Environment Assessment Web Account
Subject: Northern Pulp Effluent Pipe
Date: March 9, 2019 1:58:59 PM

Dear Environment Minister Margaret Miller,

I am writing to you about my concern with Northern Pulp's plans for an effluent discharge pipe in the Northumberland Strait. I am a resident of Pictou County, I have grown up walking the beaches, swimming in the waters and fishing in the waters of the Northumberland Strait. The idea that Northern Pulp wants to use, what I think of as my backyard, as a dumping ground for their waste is unfathomable.

We are living in a time where every action on the environment has dire consequences. The ramifications of those consequences will be felt for generations to come. One example that is ailing the Earth's ocean's right now is hypoxia zones. Hypoxia zones are areas in the ocean that do not have enough oxygen in them to support aquatic life. Sea animals that are able, avoid these areas, those that cannot may suffocate and die. That is why these areas are also known as dead zones. If Northern Pulp is allowed to put their pipe in the Northumberland Strait it will create a dead zone.

I was able to attend the open house presentation hosted by Northern Pulp back in December of 2017. an engineer and the principal consultant for process and environment with KSH Solutions was also in attendance. He was fielding many questions from the concerned populace. One of the questions I happened to ask was, will the effluent cause a dead zone? His answer was Yes. My next question was how big would this dead zone be? His answer was that they did not know. This area that people recreationally fish, boat, swim and commercially fish in would be dead, how far reaching that could be is unknown. That is a frightful thought.

Table E.1.1-1 (Summary of Project Related Residual Environmental Effects) in Northern Pulp's EA shows that there is no significant residual environmental effect on harbour water quality, marine fish or marine fish habitat. I disagree with their findings as I would define a dead zone as a seriously significant environmental effect. This is an issue that is not covered well in Northern Pulp's EA and requires more thorough investigation. I believe as Environment minister you need to request an Environmental Assessment Report.

On Nov 7, 2016 the Federal Government launched the Oceans Protection Plan. It notes that Canada has the world's longest coastline and the Ocean is one of our most important resources. Should we not follow along with that mantra and do our part to protect our oceans, our resources. Planet Earth is a place of finite resources and capabilities to rehabilitate itself. Please do the right thing as environment minister and protect the environment.

Sincerely,

From: noreply@petition.web.net
To: Environment Assessment Web Account
Subject: In support of Northern Pulp"s EA application
Date: March 9, 2019 2:11:30 PM

I am writing in support of the Environmental Assessment application submitted by Northern Pulp for its new treatment facility.

A lot has been said about Northern Pulp and its impact on the local community. I stand in agreement with many, including Unifor, that Boat Harbour must close and be cleaned up to respect Pictou Landing First Nations people and their land. I also know there are many positives about having 300 good-paying jobs in Pictou, supporting thousands more across Nova Scotia, particularly in rural communities.

The Nova Scotia Environment Act is an essential piece of legislation designed to protect our shared environment and guide our economic development. The Act rightly spells out its purpose through a set of principles for sustainable development that should guide its application, including:

------> The linkage between economic and environmental issues, recognizing that long-term economic prosperity depends upon sound environmental management and that effective environmental protection depends on a strong economy.

In this situation, science should determine the best path forward. Nova Scotia, along with the rest of Canada, has among the highest global standards for environmental stewardship in the forestry sector.

The job of government and every person we elect to represent us in government is to find the best way forward when there are many competing and sometimes opposing interests. Communities across Canada manage to find a fair balance where good mill jobs coexist with a prosperous fishing industry and thriving communities.

We can and must find this balance for Pictou. There is a lot at stake: jobs, the environment, and respect for First Nations. We can and must find a solution that supports all three.

Thank you.

To: @gmail.com>

Dear Minister Margaret Miller,

My name is from Belfast PEI.

I am writing today with extreme concern over the proposed application for Northern Pulp to pump 70 - 90 000 000 liters of effluent a day into the Northumberland Strait.

There are so many aspects to this file that it could take days to explain but to put it short, Northern Pulp wants the fishing industry in NS, PEI and NB to take 100% of the risk on whether this effluent will affect lobster, lobster larvae, Herring, mackerel, rock crab and tuna stocks.

We know that the government of the day in the mid 60s along with Scott Paper told Pictou Landing First Nations that the water /effluent going into Boat Harbour would be clean and that it would not affect fish or habitat in that estuary. Within a week, all fish were floating on the surface dead, and now 52 years later Boat Harbour is a toxic waste dump that looks like something from a science fiction movie. It is disgraceful and the PLFN and the residents of Pictou have lived with this far too long. I applaud your govt for sticking to the 2020 deadline to shut Boat Harbour down.

Boat Harbour has been catching the dioxins, furons, cloride, Clorine Dioxide, mercury and other toxic metals for 52 years. It gives the effluent 30 days to cool while the toxic chemicals settle out. The new proposed process would see the effluent treated for hours, then solids ,chemicals ,toxins, and all be pumped directly onto Prime lobster, crab, Herring, mackeral and tuna habitat and fishing grounds.

Northern Pulp does NOT know the make up of the chemicals that will be in the effluent, they told us that. I asked in a meeting in New Glasgow, the fall of 2017 with Northern Pulp and 350 fishers, where the studies are that prove that this new proposed effluent will not harm lobster larvae ?? All their high priced lawyers and consultants at the meeting just looked at each other then admitted publicly that they did not study that at all,,,, "but don't worry, it will be fine". Can you imagine? The whole basis of our industry is larvae and they didn't even test it !!!!!

The water proposed to be dumped is fresh water and is significantly hotter than the receiving water, and we know scientifically that warm fresh water itself will kill lobster larvae, let alone the toxic soup and solids that will be pumped out with it. Salinity and temperature affect lobsters a lot. Ask SW Nova lobster buyers that hold lobsters in out door pounds what happens to lobsters if it rains hard. Also, we keep thermometers in our Lobster traps in 4 or 5 different locations throughout the season, if the temperature changes more than 2 degrees up or down it affects how they trap. I have seen them hide for days till the temperature stabilizes. The proposed effluent is over 20 degrees hotter than the receiving water. They will not stay in the area. That doesn't even factor in the chemicals and solids. The solids will be laced with chemical, fish are curious, anything with a different smell or taste they assume is food. Little would they know they would be poisoning themselves.

Then we asked Northern Pulp about ice cover and how it affects dilution and mixing ?? Again, they didn't know and did not think about that.... Or test it .

We told them at the same meeting that there was not enough water depth in Pictou Harbour to run the pipe, because the ice would crush it. They said no it will be fine. Well after 3 different survey crews at work in 2018 they all concluded that Pictou Harbour is too shallow, the pipe would get crushed by ice.

This company Paper Excellence Has 5 other pulp mills in Canada, 2 of them, Meadow Lake Saskatchewan and Chetwin BC have closed looped effluent treatment facilities that recycle their effluent. I proposed this technology as a solution for the Pictou Mill but Northern Pulp did not want to talk about it, " cost being the factor"..... Our environment is just as important as Western Canada's environment is !!!!

They said, that during the Kraft process using Clorine dioxide for bleaching (like at the Pictou Mill now) if used in a closed loop, it will destroy (eat through) the piping system. So I said let me get this straight, your effluent will eat through metal pipes, but NOT hurt baby lobsters suspended in it ??? Nothing but silence.....

They would need to change the process to peroxide bleaching for a closed looped system so that the pipes would not be ruined. But Northern Pulp is not interested investing the required dollars to change the plant.

The NS Government finds themselves in a spider Web of conflicts of interest on this file that the public are just finding out about now.

Some of he glaring ones are, because of the 1995 endemnity agreement, the province of NS have to pay for the future cleanup of Boat Harbour, the construction of the New Treatment Facility and outfall, they are paying for the environmental report of the new treatment facility for Northern Pulp, they have to pay for any shut down time for the mill if closed before 2030 and they want to consider a class one in house provincial environmental assessment, that can be signed off by themselves.....

The Premier of NS of the day mid 1990s is now the Chair of the Board for Northern Pulp,

and the lawyer that wrote the endemnity agreement in 1995 is a deputy Minister under Premier MacNeil now.

So how can we POSSIBLY get a fair, transparent, detailed environmental assessment from a fast tracked provincial class 1 ?? This project affects 3 provinces and the proposed site is in Federal jurisdiction waters. DFO, Transport Canada, and Environment Canada need to be involved to protect our Industry. The Federal Government is changing the Oceans Act and the Canada's Ocean Protection Plan, and they like to wave the environmental flag around the world. Marine Protected Areas are a big topic right now across Canada. This very location that Northern Pulp has picked for the outfall pipe, is a "Marine Refuge" officially designated by DFO, Meaning it is Prime fishing grounds and is protected, it is part of the MPA process. How could it be used as an Industrial toxic dump zone ?? Seriously?? 90 000 000 liters a day of unknown effluent with 4 tonnes of solids mixed in ??? Dumped on a Marine Refuge. !!!!

Let's talk about what we know for a fact, Stantec has been involved for years with Northern Pulp and have done air quality reports and most recently completed a 129 page receiving water study.

This report does not say what is in the effluent under the new proposed treatment facility outfall, heavy metals, solids, chemicals etc , or like I mentioned earlier, how it would affect lobster larvae, adult lobster, Herring spawn, mackerel spawn, crab larvae, or their habitat..... Or how ice cover like we have "right now" would affect mixing and dilution. There are NO reassurances and fewer guarantees.

The reason I raise this point is because Stantec was heavily involved in the environmental impact report and engineering of the Confederation Bridge. They gave it the All Clear, despite a team of scientists including David Suzuki that said there were 1200 possible environmental affects. David Suzuki said to build the bridge in the Northumberland Strait would be "monumental stupidity". And it is built directly on the biggest earth quake fault in the Northumberland Strait....

Well hind site is 20/20 and we know now who was right.

I was fishing with my father at the time, and prior to the bridge ,catches off of Point Prim 45kms east of the Bridge were 20 -30 000lbs per spring season. As soon as construction started in Oct 1993, the following spring there was a major decrease in catch, and by 1997 when the bridge was finished catches had dropped to 5000lbs of lobster for an entire season. After 4 years catches came up to 10 000 lbs, then slowly rebounded to 15000lbs but it took 18 years to get over 18000lbs and now 22 years later the catches finally came back to previous levels.

However, over 40 % of the Lobster Fishers on PEI from Wood Islands to Victoria in the spring were forced out of business due to catches being so low for so long. Also the fall season from Victoria to Egmont Bay saw similar results. NB and NS coasts 60kms on either side of the Bridge faced the same fate.

Fishers had to sell their licenses to Fishers in Beach Point east, and to West Point west, to get far enough away from the Bridge where the affects were not as drastic. The Federal govt came up with a buy back program 7 years ago as well to buy back some of the older fishers, once it realized the extent of the damage that was done. But the money paid for the few licenses that they bought was a fraction of the value of a license today.

The Biggest noticeable change was the silt in water column, we used to be able to see the ocean floor in 20' of water. From 1994 - 2006 we could not see 3' into the water due to silt. This affected the lobster, Herring, mackerel, tuna and scallops as well. After 2006 it slowly started to clear again and now it is like before. However, we hardly would see barnacles on buoys and never on traps. Now the buoys are covered a half inch thick with them and the traps as well. We have to use paint scrapers to get them off.

Another change was the increase in tidal currents. They built the bridge directly on the

narrowest part of the Strait, 44 piers, which created a venturee affect increasing the tide by 30%. Before the bridge our buoys would sit on top of the water and never pull below the surface. From 1996 on, since the Piers were placed, the currents now pull the buoys completely under water out of site. We had to add 4 fathoms of extra buoy line to our Lobster and crab gear in order to retrieve it.

The increased silt drove lobsters to the North side of PEI, we know this because the same amount that the catches in LFA 25 and LFA 26A were down, LFA 24 increased the same amount.

Another affect was the introduction of foreign invasive species like tunicates (5 different types) and green crabs. All 6 of these species were never here before and are not native to the Gulf of Saint Lawrence. We found out they arrived attached to the hull and in the bilge water of the HLV Svanen, the Dutch built, world's largest ocean Crane brought here to place the bridge sections.

The tunicates devastated the mussel industry on PEI, (Canada's largest mussel source) and drastically affected the oyster industry. Green crabs also targeted oysters and both them and tunicates are still a huge problem today costing these industries tens of millions of dollars to combat them every year.

All of these things actually happened in real time, despite "Stantec" and others stating that the fishery would not be affected and not to worry.....

The PEI government since 1996 have had a lobster index program and a Sea Sampling data base. Every year, spring and fall, provincial government Biologist come out onboard 5 times throughout the season in 60 harbours around PEI to measure every lobster that comes aboard, undersize, berried females, window females, legals etc etc. The boats involved in the program, which I am one, record their catches and window females every day in a logbook. Now we have 23 years of lobster science on PEI, DFO ( ) admits that PEI has the best, most accurate lobster science in the world. If you have any questions on the data or the program, call PEI Lobster Biologist Robert MacMillan or at RJMACMILLAN@gov.pe.ca

We are Very Very concerned about the unknowns on this proposed new treatment facility/effluent for Northern Pulp. Their track record in Pictou and around the world with their parent company Paper Excellence has a dismal reputation. It seems they will do near anything for profit. Our industry is too valuable, and you as a Minister have an obligation to make sure that things are done right. The work is not done,,,,,,and the 1700 page proposal does not answer the real questions that our industry needs answered.

Northern Pulp knew 4 years ago that the deadline was 2020. "They" decided to do nothing for 3 years, now they are pressuring you to make a rushed last minute decision.

The 1200 environmental affects of the Bridge were "risk managed" and or "mitigated" away. Some fishers in Borden PEI and Murray's Corner NB got a one time compensation check of $10 000. Meanwhile they were forced out of business, and the fishers from Egmont Bay, Summerside, Nine Mile Creek, Point Prim, Pinette and Wood Islands got nothing. ....

The compensation package was a complete disgrace. But one thing it did do was taught us a valuable lesson that will never happen again.

If Northern Pulp and the NS Govt are so confident in the information they have now, then it won't be a problem to have a 10 billion dollar compensation plan insurance policy in place.

Like I said before, 100% of the risk is on us right now, and that is NOT an option.

The more transparent and thorough way to handle this would be for you as Minister to reject this current proposal ,and to call for a full indepth , Federal Environmental Assessment with CEAA. This will serve to protect your office and Ministry as well from 100% of the Liability if things go wrong. Noone wants their legacy to be a devastated natural resource.

In December 2017, Environment Canada officially listed "Kraft Pulp Mill Effluent" as a

"Toxic Substance".....

The lobster Industry in the Maritimes was worth 2.4 Billion dollars in 2018, and has been over 2 Billion a year for many years. A big portion of this Industry Is in the Northumberland Strait. We know from Giro studies that the water in the Pictou Area " Giros" (stays in the area) for 5-6 weeks and up to 12 weeks in certain conditions. Lobster larvae float in the top 3' of the water column for 6-8 weeks every summer. This concentration of toxic effluent and it's affects have not been factored in.

The Marketing of " Canadian" Lobster as a whole could also be affected. Remember the "one" Mad Cow from Alberta, how it devastated the Beef Industry across Canada for a decade. The full costs are still not known today but it's in the 10s of Billions. It's only the last few years that that Industry has recovered.

Only court orders have forced this company and previous owners of the Mill to pay fines for repeated effluent spills, contamination and repeated air stack test failures.

We Need your help Minister Miller ! Please reject this current Northern Pulp treatment facility /effluent discharge proposal and call for a Full, detailed, transparent and thorough Federal Environmental Assessment through CEAA, so that all of the required data can be found and tests completed.

I thank you for your time, and consideration.

Yours Truly

Subject: Pulp Mill Concerns
Date: March 9, 2019 2:20:07 PM

Dear Environmental Minister Miller

I am writing to express my concerns about Northern Pulp's plans and I implore you to reject their proposal, or at the very least, order an environmental assessment report. The decision of whether or not the mill's continued operation will have adverse effects to human health and cause unmitigated environmental damage is a no brainer. If you look at the fact that the mill's presence is proven to cause cancer in the inhabitants of the area, it seems that it is quite clear that the continued operation will no doubt have adverse effects to human health. This quote from the Halifax examiner says it all really: "Dalhousie University researcher has come forward to defend her 2017 ambient air quality study about cancer-causing air emissions detected near the Northern Pulp mill after finding that her study was "misrepresented" in the mill's recently registered Environmental Assessment [EA] for its proposed effluent treatment facility." Whether or not the law recognizes a person's right to a clean and safe environment, logic and compassion for other humans should tell us that people should not have to live with a corporation moving in next door and harming their health. It is also ridiculous to think that merely closing boat harbour is in any way ending the environmental racism that is the mill. The fact that one of their most valuable resources was allowed to be destroyed by Northern Pulp is criminal, and if you are trying to do right by them, obviously you cannot allow the culprit to continue to poison their air!

They are dumping their effluent straight into the ocean. Why must we say more? This is supposed to be Canada's ocean playground for god sake. When you have local fishermen who are telling you that this is a terrible idea, that should be taken seriously. These people work every day out on the strait, and they are the industry that defines Nova Scotia. They don't sell Nova Scotian craft paper at the airport do they?

Sincerely yours,

Subject: Proposed Project Comments
Date: March 9, 2019 2:38:08 PM

Project: replacement_effluent_treatment_facility_project Comments: The Honorable Margaret Miller Environmental Assessment Branch Nova Scotia Environment P.O. Box 442 Halifax, NS, B3J 2P8 Dear Minister Margaret Miller, The purpose of this correspondence is to ensure that the â?oReplacement Effluent Treatment Facility ETF Projectâ? submitted by Northern Pulp Nova Scotia Corporation NPNS, is subject to a full panel Federal Environmental Assessment EA. Â I am writing you this letter today as a Nova Scotia Taxpayer, a proud and long-time resident of Pictou County, a First-Generation Fisherman and a soon-to-be father. The feeling of making your living on the water, watching the sun rise and set each day, working hard in hopes of being rewarded so that you can support your growing family â?" there is no better feeling. As a Fisherman of Lobster Fishing Area 26A LFA 26A, the proposed effluent discharge pipe will dump millions of litres of effluent, every 24 hours, within the grounds upon which I fish. This effluent will also carry approximately 945 kg of solids into the Northumberland Strait each day that were not previously reaching the strait. This not only puts my livelihood at risk, but also hundreds of others who rely on the catches in LFA 26A. According to Northern Pulp, the probability of this treated effluent negatively impacting the fishery is highly unlikely. Based on similar promises made to the first nations and the environmental disaster that became Boat Harbour, it is my belief that Northern Pulp cannot be trusted. Allowing a pipe to pump millions of litres of effluent directly into the strait without confidently knowing the environmental impacts, tourism fishing industry impacts - should NOT be a risk this government is willing to take.
worked their entire careers at the mill â?" they both died of cancer.
. While I am not solely blaming this on the mill, studies have shown that Pictou County has the highest rates of cancer incidence in Nova Scotia. These same studies discuss the pollutants entering the air, from the mill, as being the likely cause. Not only is Northern Pulp a risk to the marine environment, but also to the health of the thousands of residents of Pictou County. In light of the fact that their practices have been questionable for 60 years, they should be subjected to the highest level of federal environmental assessment. It is my belief that it is your mandate to protect the environment from unreasonable human activity, and to protect humans from unacceptable environmental risk.Â With that in mind, I am asking you to please ensure that Northern Pulpâ?Ts â?oReplacement Effluent Treatment Facility ETF Projectâ? is subject to a full Federal Environmental review. Thank you. Name: Email: @gmail.com

Subject: In support of Northern Pulp"s EA application
Date: March 9, 2019 3:25:59 PM

I am writing in support of the Environmental Assessment application submitted by Northern Pulp for its new treatment facility.

A lot has been said about Northern Pulp and its impact on the local community. I stand in agreement with many, including Unifor, that Boat Harbour must close and be cleaned up to respect Pictou Landing First Nations people and their land. I also know there are many positives about having 300 good-paying jobs in Pictou, supporting thousands more across Nova Scotia, particularly in rural communities.

The Nova Scotia Environment Act is an essential piece of legislation designed to protect our shared environment and guide our economic development. The Act rightly spells out its purpose through a set of principles for sustainable development that should guide its application, including:

------> The linkage between economic and environmental issues, recognizing that long-term economic prosperity depends upon sound environmental management and that effective environmental protection depends on a strong economy.

In this situation, science should determine the best path forward. Nova Scotia, along with the rest of Canada, has among the highest global standards for environmental stewardship in the forestry sector.

The job of government and every person we elect to represent us in government is to find the best way forward when there are many competing and sometimes opposing interests. Communities across Canada manage to find a fair balance where good mill jobs coexist with a prosperous fishing industry and thriving communities.

We can and must find this balance for Pictou. There is a lot at stake: jobs, the environment, and respect for First Nations. We can and must find a solution that supports all three.

Thank you.

Re: Replacement Effluent Treatment Facility (ETF) Project for Northern Pulp

I am a resident of the Town of Pictou who is very concerned about Northern Pulp's Environmental Assessment (EA) application. After reviewing the company's application documentation, I remain wholeheartedly opposed to the proposal because i) many aspects of the proposal are inconsistent with the principles of sustainable development that are supposed to be protected with the *Environment Act,* ii) the information provided in the documentation is misleading, and iii) there is a lack of trust that, if approved, Nova Scotia Environment has the capacity to monitor and enforce compliance with regulations. Each of these points will be addressed separately below.

i) The proposal is inconsistent with the principles of sustainable development protected by the *Environment Act.*

The proposal is inconsistent with the principles of sustainable development that are supposed to be protected with the *Environment Act*. In particular, the absence of critical information in the application documentation suggests that the precautionary principle identified in Nova Scotia Environment's Guide to the Environment Act (https://www.novascotia.ca/nse/ea/docs/EAActGuide.pdf) ought to outweigh any other consideration. According to the precautionary principle, an activity whose effects are disputed or unknown should be avoided, and therefore, the proposal ought to be rejected because:
• The final characteristics of the effluent are admittedly **unknown** by Northern Pulp and will remain **uncertain** until the new treatment system is up and running as indicated in Section 9.0 Human Health Evaluation, page 502,
"there is presently uncertainty regarding the likely chemical composition and characterization of the marine treated effluent discharge (including the potential concentrations of substances in the effluent"
• The proposal does not include lobster larvae tests or tests on herring spawning grounds, thereby indicating these effects are **unknown**. This is a particularly glaring omission given that these tests were specifically requested by those directly affected by potential negative effects of the effluent.

• The proposal does not mention the known mercury contamination in the soil and bedrock proximal to the proposed new treatment plant and basins, nor does it acknowledge the potential for disturbing the mercury contamination during construction. (Baxter, J., The Canso Chemicals mystery: With the chemical plant long gone, why is the company still alive? And what about all that mercury pollution?, *Halifax Examiner*, March 7, 2019, https://www.halifaxexaminer.ca/province-house/the-canso-chemicals-mystery-with-the-chemical-plant-long-gone-why-is-the-company-still-alive-and-what-about-all-that-mercury-pollution/). Yet, Section 2.5.2 (p.15) of the proposal explicitly identifies that siting decisions of the treatment facility were made with consideration for sensitive environmental features and that mitigation and compensation measures were developed where avoidance was not possible. "NPNS has emphasized project design and siting so that the location and configuration of the project facilities considers the above measures wherever possible so as to avoid or minimize the potential environmental effects of the project. To the extent possible, project facilities have been sited to avoid and reduce interactions with watercourses, wetlands, areas of elevated archaeological potential, and other sensitive environmental features. Where avoidance was not possible, mitigation or compensation measures have been developed as part of the EA, and will be implemented in consultation with the applicable regulatory authorities."
It is a gross oversight that the potential disruption of mercury contamination has not been addressed in the proposal and one can conclude that, on the basis of this proposal, the potential risk of mercury disturbance that, while present, is **unknown**.
• Northern Pulp has exhibited a poor track record with their current pipe, experiencing a number of breaks and leaks in recent years. Northern Pulp's inability to effectively maintain the integrity of their equipment over time would suggest that the ability of the company to prevent environment damage from effluent pipe breaks in the future is **uncertain** at best, not in keeping with the precautionary principle, and, therefore, too risky a prospect.
• Finally, the new effluent treatment system requires burning sludge, but the proposal does not indicate additional pollution abatement equipment that will be a part of the power boiler stack to minimize environmental impacts of burning something with **unknown** characteristics. This lack of information is particularly troubling given Northern Pulp's historical problems with the power boiler pollution filtration and the limited stack testing currently required. Furthermore, while Northern Pulp has had permits for test burns of sludge in the past, those test burns offer no assurance the sludge burning with the new system would be safe since effluent processing is entirely different and the sludge will be different given that it will undergo less 'polishing'.

ii) <u>Some of the information provided in the application is misleading.</u>
Some of the information provided in the application is misleading, specifically with respect to the quality of effluent that will result from the new treatment facility.
• First, in the public information sessions presented by Northern Pulp in December 2017, the effluent quality promised was contingent on Northern Pulp installing an oxygen delignification system. The proposal has been revised since the plans presented in 2017, but the promise of improved effluent quality remains despite oxygen delignification not being part of this proposal. If oxygen delignification is required to achieve the predicted effluent quality as promised, why is it not included in the proposal? And, if the proposal is assessed at face value and approved based upon predicted effluent quality dependent upon oxygen delignification, but oxygen delignification is not proposed, can the facility proceed and have poorer quality effluent as a result?
• Second, Northern Pulp's promise of improved effluent quality is misleading based upon the company's own admission in internal communication. Despite publicly claiming the effluent will be better, internal documents acquired by environmental lawyer Jamie Simpson acknowledge that it will, in fact, be worse due to losing the 'polishing' time that Boat Harbour

affords. (Jamie Simpson's interview with CBC Information Morning can be accessed here: https://www.cbc.ca/listen/shows/information-morning-ns/segment/15672343)
• The two points above refer to promises by Northern Pulp that effluent quality will be improved. Yet, as previously indicated, by the company's own admission, the actual characteristics of marine effluent are unknown. Therefore, it is challenging to understand how a promise of improved effluent quality can be made, if the effluent characteristics are uncertain.
• In addition, the author of one study cited by Northern Pulp in their EA proposal has recently responded to the interpretation of their work within the EA document and have explicitly stated that Northern Pulp has misrepresented its scientific contribution, thereby raising concern about the representation of other studies included in the proposal (Pannozzo, L., Dalhousie researcher breaks silence over pulp mill's cancer-causing air emissions, *Halifax Examiner*, March 7, 2019, https://www.halifaxexaminer.ca/province-house/dalhousie-researcher-breaks-silence-over-pulp-mills-cancer-causing-air-emissions/).

iii) There is a lack of trust that, if the project is approved, Nova Scotia Environment has the capacity to monitor and enforce compliance with regulations.

• Lastly, there is a lack of trust that Nova Scotia Environment has the capacity to monitor and enforce compliance with regulations or adequately monitor the terms and conditions of this environmental assessment, should it be approved. The provincial Auditor General has identified this specific issue as a concern as recently as 2017 where his November 2017 report clearly stated that "Nova Scotia Environment is not monitoring terms and conditions attached to approved projects", (Report of the Auditor General to the Nova Scotia House of Assembly, November 1, 2017, p. 45; https://oag-ns.ca/sites/default/files/publications/FullNov2017_1.pdf). And, using history as a guide, NSE has demonstrated numerous challenges with effectively monitoring Northern Pulp and enforcing the regulations it has imposed as highlighted below.
• Nova Scotia Environment (NSE) has the responsibility of creating and enforcing the rules for Northern Pulp's current effluent pipe, yet there have been at least three pipeline leaks in recent years (2008, 2014 and 2018). And, despite increasing efforts by the regulator to improve pipeline monitoring by the company in response to the recent pipe breaks, those efforts did not result in preventing future leaks.
• The current monitoring and enforcement model employed by Nova Scotia Environment (NSE) requires companies self-report problems and breaches. More than a decade ago, in 2008, a review of NSE by the Office of the Auditor General identified this as an area of concern and recommended that,
"The Division should establish procedures to obtain objective evidence to validate the accuracy of monitoring reports received from approval holders". (Recommendation 3.2, https://oag-ns.ca/sites/default/files/publications/2008%20-%20Feb%20-%20Ch%2003%20-%20Environment%20and%20Labour%20-%20Env%20Mon%20and%20Compliance.pdf)
Yet, the 2017 Report to of the Auditor General to the House of Assembly (https://oag-ns.ca/sites/default/files/publications/FullNov2017_1.pdf) notes that this recommendation had not yet been addressed. As a result of failing to implement a solution per the Auditor General's decade-old recommendation, NSE has proven to have lessened awareness of certain problems and have been unable to minimize what could be preventable environmental damage. Some examples that illustrate NSE's limited objective oversight with respect to Northern Pulp include the following:
o Northern Pulp had problems with their power boiler scrubber identified to them by a consultant in 2006, but NSE did not become aware of the situation until 2008. Had NSE been

relying on objective oversight, the problem could have been identified much sooner rather than obliviously allowing the company to continue operations.
o Subsequently, NSE issued an industrial approval in 2011 despite the company failing to address their air pollution problems. The Minister of the Environment stated that NSE was unaware of the ongoing air pollution issues when the 2011 Industrial Approval was issued despite evidence to the contrary provided by NSE to the environmental group Clean the Mill (CBC News, Northern Pulp air quality monitors years behind schedule, October 7, 2014, https://www.cbc.ca/news/canada/nova-scotia/northern-pulp-air-quality-monitors-years-behind-schedule-1.2789892). It was not until 2012 that NSE finally issued a directive to the company to address the problem. This example illustrates a lack of communication within NSE, further reinforces the need for objective information to be used in decision making within the Department in order to prevent damage from environmental regulation violations and further justifies the decreased public trust in NSE's ability to protect the environment.
o When the effluent pipe broke in 2014, NSE grossly underestimated the volume of effluent lost at be 4 to 5 million liters ((CBC News, Northern Pulp charged with releasing effluent into fish habitat, October 14, 2015, https://www.cbc.ca/news/canada/nova-scotia/northern-pulp-spill-charge-1.3270154). However, the actual volume released turned out to be 47 million liters which was only revealed in court proceedings after a federal investigation (Withers, P., Northern Pulp fined $225K for 'toxic' effluent pipe leak, CBC News, March 23, 2016, https://www.cbc.ca/news/canada/nova-scotia/northern-pulp-mill-effluent-leak-fine-1.3504203). NSE has no way to independently monitor the current pipe or that proposed in this EA application not does it have the ability to validate the information reported by the company. As a result, NSE must rely on the face value of information provided by the company, a situation that has proved problematic in the past.
o Despite Northern Pulp's 2015 Industrial Approval requiring the company 'operate and maintain real time flow monitoring equipment ... designed to immediately notify the approval holder in the event of a total loss of flow or a reduction of flow below normal operating conditions', it was a member of the public that identified and reported the most recent pipe leak in October 2018. (Brimicombe, H., Northern Pulp line springs another leak, *The Advocate*, http://pictouadvocate.com/2018/10/24/northern-pulp-line-springs-another-leak/).
• Where Northern Pulp's information has proved inaccurate in the case of the 2014 pipe break, was missing in the case of the malfunctioning power boiler scrubber between 2006 through 2008, and the public needed to report the pipe break case of 2018, it seems unrealistic to think that NSE has the capacity to effectively monitor a new pipe and proactively limit environmental risks.
• Over the years, NSE has issued multiple directives to Northern Pulp to correct air emissions violations. Yet, these directives were ineffective at generating an immediate solution. Instead, Northern Pulp was given excessive timelines (often years) to correct problems. If a problem occurs with the proposed pipe or at the proposed new on-site treatment facility, problems need to be able to be identified and addressed immediately not with the excessive timelines we have become accustomed under the current monitoring and enforcement model. There is no amount of time that would be acceptable to fix problems that risk damaging the Town of Pictou's watershed or the commercial fishery.
In summary, I remain wholeheartedly opposed to Northern Pulp's effluent treatment proposal. Several aspects of the proposal are inconsistent with the principles of sustainable development that are supposed to be protected with the *Environment Act*. The information provided in the proposal documentation is misleading. And, finally, there is a lack of trust that, if approved, Nova Scotia Environment has the capacity to monitor and enforce compliance with regulations.

Sincerely,

RE: Response to Northern Pulp Nova Scotia

Replacement Effluent Treatment Facility

In response to the proposal from Northern Pulp to pipe effluent into the Northumberland Strait I have several concerns regarding the lack of information provided in this document.

I am not a scientist or engineer, I am a concerned resident who has lived with air emissions that have exceeded the conditions of the IA over the course of that last several years. I have lived through two recent pipe ruptures which have allowed untreated toxic waste to foul the land and water. Both pipe breaks were discovered by individuals while out walking. One resulted in a fine and the investigation is still ongoing regarding the latest spill/breach.

The lack of information regarding what will be discharged is most concerning. As Paper Excellence operates a number of bleached kraft mills throughout the world this information should be readily available and should have been included in this proposal. To state they won't know what will be going into the Northumberland Strait until the system is operational is highly questionable.

What is different in this proposal, submitted by this same mill, from two previously proposals

(1990's)regarding piping effluent into the Northumberland Strait which were rejected?

Why is the technology/system presented in this proposal from a mill operation that was never built, rather than one that is operational?

Currently the effluent flowing into Boat Harbour is released into the Northumberland Strait after treatment and 'polishing' for 25 to 30 days. The new system will release effluent into the Northumberland Strait in a matter of hours at a rate of 70-90 million liters of hot liquid and 945 kg of solids every twenty four hours.

There is a great deal of technical theory, not proof in this proposal that there will be no ill effects to the receiving waters (Northumberland Strait) similar to information presented when Boat Harbour was built. Once the effluent was discharged into Boat Harbour every living thing was dead within days and created an environmental disaster that will never be free of toxins even after a multimillion dollar 'clean up'. The receiving waters (over 300 acres) of Boat Harbour contains heavy metals, mercury, zinc, chromium, cadmium, lead, nickel, arsenic, aluminum and vanadium. I cannot trust this same fate will not happen to the Northumberland Strait.

I also have grave concerns regarding the burning of toxic solid waste in an antiquated boiler without constant monitoring. Northern Pulp has an extensive record of noncompliance to their IA conditions when it comes to air emission.

Northern Pulp has presented a proposal that has very little actual fact based information and a great deal of speculation or theory.

I am concerned for the thousands of fisheries related jobs that will be put in jeopardy if an effluent discharge pipe is permitted in the Northumberland Strait. I am concerned the marine environment and ecosystem will be destroyed as well as our tourism industry. But most of all I am concerned with the health and wellbeing of everyone living in Pictou County.

There is far too much at risk to allow this proposal to be approved and I respectfully suggest this proposal should be rejected as presented.

Respectfully Submitted

Project: replacement_effluent_treatment_facility_project Comments: Yes this project should get approved, if we look around Nova Scotia itâ?Ts clear to see that the province is turning into a retirement community and less industry is looking to set up shop in our province,There is no reason why the fishing industry and pulp/forestry industries cannot both be sustained here in Nova Scotia as they have for the last 50 plus years, there is more than enough science to support the fact that this effluent treatment plant will look after any concerns around environmental upsets as this type of plant is in place in many other places in North America. Subject: [PROBABLE-SPAM] Northern Pulp Pipeline Objection
Date: March 9, 2019 4:14:31 PM
Attachments: image002.png

To whom it may concern.

I object to the approval of a new pipeline for Northern Pulp (Paper Excellence) for the following reasons:

Northern Pulp has not honestly submitted the all the information available to them.

Namely,

Internal emails that received through a FOIPOP request show that Dillon consultants raised the issue of heavy metals, such as mercury, and of dioxins and furans in the effluent. In January 2018, Dillon sent a list of questions to Northern Pulp, KSH Consulting, and TIR, saying it needed information on the "percentage of dioxins and furans in the final effluent going into the straight [sic] daily."

In February 2018, Dillon again wrote to Northern Pulp reminding the technical manager of the need to acknowledge these substances, noting that:

… questions have arisen regarding the content of metals in the discharge. Based on available data …[redacted] will review potential metals or other effluent components levels in the context of potential marine environmental risk …

And:

We believed [sic] that an understanding of effluent characteristics regarding metals, dioxins and furans will be necessary.

Also, the new pipeline necessitates the burning of solid waste through their already inefficient burner systems creating further air pollution. The current air pollution according to a Delhousie study is already a significant health hazard to the general population in the area.

Please read the following article,

Dalhousie researcher breaks silence over

pulp mill's cancer-causing air emissions

MARCH 7, 2019 BY LINDA PANNOZZO6 COMMENTS

Share this story

Dalhousie University researcher Emma Hoffman has come forward to defend her 2017 ambient air quality study about cancer-causing air emissions detected near the Northern Pulp mill after finding that her study was "misrepresented" in the mill's recently registered Environmental Assessment [EA] for its proposed effluent treatment facility. [1]

In Part 3 of the "Dirty Dealing" series, I reported that a study by Hoffman and five other Dalhousie University researchers revealed that air levels of three of the seven volatile organic compounds (VOCs) assessed near the Northern Pulp mill exceeded cancer risk thresholds.

Over an eight-year period (2006-2013), 1,3-butadiene, benzene, and carbon tetrachloride were found to routinely exceed US Environmental Protection Agency (EPA) cancer-risk levels, which refer to the probability of contracting cancer if exposed to a concentration of a substance every day over the course of a 70-year lifetime.

According to the public and peer-reviewed study published in *Environmental Science and Pollution Research* — one of the few on record about airborne VOCs in rural Canada — many VOCs are either known or suspected of having direct toxic effects on humans, ranging from carcinogenic to neurotoxic and that "combinations of air toxics may have additive or synergistic adverse health effects." By analyzing the available data, the study authors were able to show that the Abercrombie pulp mill (currently Northern Pulp) was a likely source of the contaminants.

At the time, I contacted both Emma Hoffman and Tony Walker, two of the lead researchers, to ask about their work but neither were able to speak to me. They both cited "ongoing consultations" with the Boat Harbour Remediation Project. Hoffman said she was unable to speak "due to the sensitivity of the subject matter." Both are members of the Boat Harbour Environmental Advisory Management Committee (BHEAC), which was formed in 2016 after the governing Liberals set in law the January 2020 closure of Boat Harbour as Northern Pulp's waste lagoon. At the time, the provincial department of Transportation and Infrastructure Renewal handed over the responsibility for the remediation of Boat Harbour to Nova Scotia Lands Inc., a crown corporation, which is now the proponent of the project.

Minutes obtained from the BHEAC meetings dating back to 2016 indicated at the time that the consultants, including Hoffman, were instructed to avoid speaking publicly since the subject matter was "sensitive… until [the] strategy is finalized."

Emma Hoffman, from her Linkedin page.

But Hoffman, who is still involved with separate Nova Scotia Lands-funded studies, has decided to speak publicly now, given that the ambient air study was not funded by the province. She also said she wanted to "defend" the study "due to the misrepresentation put forth by [Northern Pulp's] Environmental Assessment of the scientific contributions it

provides."

Hoffman's full statement provided to me in response to Northern Pulp's EA can be found here**.** Her supervisors and study co-authors, Dr. Judith Guernsey and Dr. Tony Walker also contributed to her statement. [2]

Northern Pulp says Hoffman's study is flawed

The Northern Pulp EA says that the limitations of the study make it impossible to point definitively at the pulp mill as being the source of the VOC emissions. It says that while the seven VOCs referenced in Hoffman's 2017 study "may be emitted in small amounts in stack and fugitive emissions at the NPNS mill…a number of other point and mobile local sources also emit these substances within the local airshed."

In response Hoffman, Guernsey, and Walker say that the study was a "pilot" and "was not intended to provide causal evidence to implicate the mill as the sole source of the VOCs. Nevertheless, the study was able to show a very plausible association.

By analyzing publicly accessible emissions data from a provincially operated National Air Pollution Surveillance (NAPS) monitoring site located in Granton, southwest of the mill and combining this with local meteorological conditions at Caribou Point, Hoffman and her colleagues were able to show a positive correlation with wind direction and the Granton NAPS site's ambient VOC concentrations in relation to the location of the pulp mill. In other words, when the prevailing winds were blowing from the mill toward the Granton air monitor, the VOC concentrations typically went up for all of the compounds assessed, except carbon tetrachloride, suggesting that the mill is likely a contributor to the increased concentrations. "The largest point source emitter northeast of the Granton NAPS site is likely the mill," she says, but "the origin(s) of the VOCs are inconclusive."

Northern Pulp's EA also stated that the study did not attempt to rule out the contributions of other potential sources. But Hoffman, Guernsey, and Walker say this "is clearly not a true statement," and that the study did not disregard other potential sources of VOC emissions. The study openly acknowledged and discussed in detail the other potential local emission sources in the area, including a coal-fired generating station in Trenton and a tire manufacturing facility. The study even provided a map indicating these other potential sources relative to the Granton NAPS site.

Study Findings Warrant Further Investigation, says Hoffman and co-authors

Northern Pulp's EA states that "When other study uncertainties are considered… there is no current air quality issue with the seven targeted VOCs in the Pictou area." Hoffman and her colleagues say this statement is "misleading."

They say that despite some of the study limitations — including a limited number of air sampling sites in relation to the mill and the short duration of the study — the fact that VOCs routinely exceeded EPA air toxics-associated cancer risk thresholds, regardless of whether the mill contributed to these VOC levels, should not be ignored. "Absence of evidence is not necessarily evidence of absence," they say. "The limitations caused by sparse data does not necessarily mean there is no problem with air emissions in this community and there is no justification for [Northern Pulp's] erroneous conclusion."

Instead of more ambient air data, particularly in areas where there is higher residential exposure to the mill's toxic emissions, there appears now to be less. In 2015 Environment and Climate Change Canada (ECCC) decided to decommission the Granton NAPS site, the only one in Pictou County that measured VOCs.

According to the Nova Scotia Department of Environment, the Granton site was decommissioned after the feds analyzed 10 years of data and determined that the average annual levels of VOCs picked up by the monitor were "below or comparable to average levels" over time, elsewhere in Canada.

But air monitors are stationary devices meant to measure contaminants in outdoor (ambient) air. When they are located properly, like in Halifax where there is a relatively steady pollution source (cars), they can indicate levels of pollutants, like smog, quite accurately. But not so when it comes to "point sources," like the mill. One of the limitations with accurately measuring ambient point source contaminants is there is often a lot of variability.

When there were northeast prevailing winds blowing from the mill toward the Granton NAPS site, higher concentrations of VOCs were typically captured. But when the wind was blowing in another direction, it wasn't. So the high levels — the ones that routinely exceeded the cancer-risk thresholds, with the exception of carbon tetrachloride, reported by the Dalhousie researchers — were averaged down by the lower concentrations when the wind was blowing in other directions. That doesn't necessarily mean there were lower VOC concentrations in the surrounding community; it means that VOCs were likely blowing where they could not be captured by the Granton NAPS site.

The study also found that the prevailing winds (southwest) that blow toward the town of Pictou dominate during the summer months, when "people are more vulnerable to ambient air pollution exposure." In fact, because of Pictou's geography, air toxics from across the Eastern Seaboard of the United States converge with the local emission sources, including the mill, and as a result higher VOC concentrations are expected in Pictou in the summer.

The study authors point out that given Pictou's considerably larger population base, compared to the rural area of Granton, there is a need for "installing and maintaining additional strategically placed NAPS sites," to more accurately represent levels of air toxics where there is higher residential exposure.

Hoffman and her colleagues say that decommissioning the air monitor left an "information vacuum" and "only emphasizes the need for more research on these questions."

What is the cancer risk?

Northern Pulp's EA points to the study's use of USEPA cancer risk levels, which are expressed as 1-in-1 million, saying that the study authors should have adjusted the values to 1 in 100,000, in keeping with "current public health policy in Nova Scotia and most other provinces." Northern Pulp argues that this "correction would alter the conclusions of the study substantially," and that the exceedances would have been "negligible."

This will take a few steps to unpack.

First, Hoffman and her colleagues say this criticism is not relevant “given that Health Canada has no formal standards for air toxic emissions.” Many agencies and provinces use an increased chance of 1-in-1 million for expressing cancer risk.

Since there are no air toxics standards in Canada, the study authors turned to the US and the Environmental Protection Agency’s National Air Toxics Assessment (NATA), which calculates concentration and risk estimates from a single year’s emissions data. [3]

The NATA risk estimates assume a person breathes these emissions each year over a lifetime (or approximately 70 years), and establishes an air concentration value when excess cancer is observed. Hoffman, Guernsey, and Walker say the US NATA process is based on a 2005 scientific risk assessment process that established the cancer risk levels to which they compared the ECCC data. [4]

To illustrate, let’s take benzene as an example. The International Agency for Research on Cancer (IARC) has classified benzene as a Group 1 agent, which means it is “known” as being carcinogenic to humans. According to Carex Canada, a national carcinogen surveillance program that was established in 2007, there is no safe exposure level for benzene.

Hoffman’s study used the US EPA estimate that if an individual were to continuously breathe the air containing benzene at an average of 0.13 $\mu g/m^3$ over his or her lifetime (roughly 70 years), that person would have no more than one-in-a-million increased chance of developing cancer as a direct result of breathing benzene. If the exposure level goes up, so does the risk.

So, if the numbers for benzene, say, were adjusted to one-in-100,000, as Northern Pulp suggested, this would effectively increase the value ten-fold from 0.13 $\mu g/m^3$ to 1.3 $\mu g/m^3$ — meaning that if an individual were to continuously breathe air containing 1.3 $\mu g/m^3$ for a lifetime that person would have no more than one-in-100,000 increased chance of developing cancer.

But increasing benzene’s threshold concentration, as Northern Pulp suggests, does two things.

First, it does exactly what Northern Pulp said it would do: expressing cancer-risk levels as one-in-100,000 means that benzene concentrations detected at the Granton NAPS site would have been close to negligible.

But Hoffman and her colleagues point out it also does something else: It effectively increases the allowed ambient air concentration for benzene, a chemical for which there is no safe exposure. Therefore, the threshold is “less protective” of human health, they say.

In defence of the study, Hoffman, Guersey, and Walker also noted that it met all the quality control standards of *Environmental Science and Pollution Research*, the internationally-recognized, environmental science peer-reviewed journal in which it was published.

Boat Harbour could be adding to the problem

Northern Pulp’s EA also states that the seven VOCs cited in the ambient air study “are not

known (based on literature review) to be associated with pulp and paper mill activities and air emissions to any significant extent."

However, the study notes that the mill's own self-reported data show otherwise. National Pollutant Release Inventory (NPRI) data showed that in 2012 the company emitted 143 tonnes of VOCs from its stacks. In addition, an estimated 3.2 tonnes of benzene were released to the air from a stack higher than 50 metres, and 0.02 tonnes were released within 50 metres of the ground.

Hoffman, Guernsey, and Walker tell me that what's also worrying is that benzene can combine with chlorinated hydrocarbons associated with the Kraft bleaching process to form a range of toxic compounds which can become airborne. The study points out that although trichloroethylene, tetrachloroethylene, and carbon tetrachloride were not officially reported to have been released by Northern Pulp, these toxic VOCs "may become airborne through evaporation from pulp and paper wastewater." [5]

In other words, Boat Harbour — the mill's current effluent lagoon — could also be contributing to ambient concentrations of VOCs.

Despite a long history of non-compliance with regards to air emissions at the mill, and without providing any evidence of its own, Northern Pulp's EA simply concludes that when it comes to the seven targeted VOCs in the Pictou County area, "there is no current air quality issue."

It's a statement that rings hollow given that the company has failed repeatedly and spectacularly when it comes to pollution emission tests.

For instance, in 2014 the mill reported the release of 1,290 tonnes of fine particulate matter — the equivalent of 13 Irving pulp mills in one location. A lot of the excess particulate pollution at the time was blamed on a faulty electrostatic precipitator (ESP) in the recovery boiler — which was replaced in 2015 — but this still didn't address the issue of combustion gases, including VOCs. While all of the stacks at the mill would emit the cancer-causing substances, most would be coming from the recovery boiler, where the "black liquor" — the waste from the Kraft process — is burned to recover the sodium and sulphides, dispose of the unwanted dissolved wood components, and generate steam. ESP units are not designed to remove combustion gases. To do that you need properly functioning scrubbers, but the 50-year old scrubber in the recovery boiler is well past its best-before date and can't handle the high levels of pulp production now common at the mill.

Add to all this the fact that issues with the power boiler, first noted to be problematic in 2006, have never been addressed. Particulate matter emissions have been exceeded from that aging stack on numerous occasions, which is particularly disconcerting when we consider that the mill is planning on using it for a key part of its proposed effluent treatment plan: the "dewatered sludge" that would be a product of the activated sludge treatment process it proposes will be "burned along with bark in the mill's power boiler, which reduces or eliminates the problem of landfilling," according to the mill.

Not knowing what chemicals will be in the sludge, coupled with a glaring lack of properly functioning pollution-abatement equipment in the stack that will be burning it, could spell much worse air quality for local residents.

I ask Hoffman what she thinks about burning the sludge in the power boiler. While she concedes that she doesn't have "experience" with this matter, or "the knowledge of how these emissions produced by incineration would be mitigated or controlled for," she doesn't think it's a good idea.

Incineration of the sludge could result in emissions of "compounds of concern," such as heavy metals and other VOCs, she says, and "there are no standards in Nova Scotia to apply against these emissions." She notes that there are studies that investigate the re-cycling of pulp and paper mill sludge, but doesn't know if such practices would be "feasible" at Northern Pulp.

According to Hoffman, the intent of the ambient air study was to increase awareness and encourage government to "adopt more stringent air quality regulations and monitoring programs to ensure health of all citizens is safeguarded and prioritized."

In addition to the ambient air study, Hoffman was lead author on another 2015 study that highlighted the environmental impacts and lack of compliance at the mill. While Hoffman's work as a researcher with Dalhousie's School for Resource and Environmental Studies has specialized in investigating industrial pollution impacts on human and environmental health, it has been particularly focused on the reality of living near a pulp and paper mill and that's because for Hoffman, the mill is personal. She is from Pictou and says she has "a vested interest in issues surrounding local industry."

The abstract to the 2015 study concluded that, "After decades of local pollution impacts and lack of environmental compliance, corporate social responsibility initiatives need implementing for the mill to maintain a social license to operate."

That expiration date appears to be fast approaching.

Linda Pannozzo is an award-winning freelance journalist and author of two books: *The Devil and the Deep Blue Sea* (2013) and *About Canada: The Environment* (2016).

Notes:

1. A critique of the Hoffman et al. (2017) ambient air quality study can be found on pp. 504-505 of Northern Pulp's Environmental Assessment Registration Document.
2. Hoffman's supervisors from the School for Resource and Environmental Studies — Dr. Judith Guernsey in the Department of Health and Epidemiology and Dr. Tony Walker — contributed to her statement and responses to my questions.
3. Furthermore, at the federal level there are no legally binding guidelines for air pollution, only voluntary guidelines. The *Canadian Environmental Protection Act* (CEPA) outlines national air objectives and emissions standards for certain industries, but nothing is legally enforced, unlike the US, UK, and the EU, where national air quality standards do have legal teeth.
4. According to the US EPA Health Effects Fact Sheets, cancer risk when it comes to hazardous air pollutants is "the inhalation unit risk for a chemical, which is the increased probability of a person developing cancer from breathing air containing a specified concentration of the chemical for a lifetime. The inhalation unit risk is derived using mathematical models that assume a non-threshold approach; i.e., there

is some risk of cancer occurring at any level of exposure…The risk-based concentrations corresponding to a one-in-a-million, one-in-a-hundred thousand, and one-in-ten thousand excess risk attributed to exposure to the chemical are presented. This means that EPA has estimated that, if an individual were to breathe air containing these concentrations of the chemical over his or her entire lifetime, that person would theoretically have no more than a one-in-a-million, one-in-a-hundred thousand, or one-in-ten thousand increased chance of developing cancer as a direct result of breathing air containing the chemical."

5. In Hoffman et al. (2017) the reference provided is: Soskolne CL, Sieswerda LE (2010) Cancer risk associated with pulp and paper mills: a review of occupational and community epidemiology. Chronic Dis Can 29:86–100.

Finally.
The intended path of the pipeline goes over the water table that feeds Pictou town, If this pipe is ruptured by fair means or foul, the effects to the community would be significant. It could be that land shift or tree roots may rupture the pipe or perhaps more sinister, the strength of feeling against this project may attract more militant action. I believe that it would be implausible to maintain security of this facility.

Sincerely

Project: replacement_effluent_treatment_facility_project Comments: Dear Mr., Mrs. I moved here in New Glasgow, Pictou County, come work at Northern Pulp and I brought my family with me. We bought a house and become members of the community. My kids were born here and they are now in school. I am expecting the government to work with the owner to complete the new effluent treatment plant and finally close the Boat Harbour saga once for all. The price to pay to lose one of the biggest employer in Nova Scotia is too high to quantify without talking about the collapse of the forestry if the mill goes down. I personally experienced a mill closure in my hometown 15 years ago and I do not wish that on anyone. The rural Nova Scotia needs young families and not only retired people. The new ETF will have the best technology available to treat the effluent and I am expecting a fair and objective review of Northern Pulp application based on proven science and not only on people personal opinions. This province need to attract new employers but a lso need to work with the existing ones to build a long and prosperous future. Lets build a better future for our younger people to have a chance to stay at home and have good paying jobs in the private sector. Best regards, Mechanical engineer Name: Email:

Project: replacement_effluent_treatment_facility_project Comments: Re Replacement Effluent Treatment Facility Project I am currently a resident of Ottawa, but my family roots go back 200 years in Pictou County and I have a small house there that I return to every summer. You will have received many comments from many people, and many of these comments will go into extensive detail about the science and engineering involved. There will have been interpretations that support NP and interpretations that oppose that position. I wont attempt to argue technical details. I will simply argue that the level of risk is far too high to allow this project to go ahead. There is far too much uncertainty involved given all thats at stake for the fisheries, for tourism, for relations with First Nations, and for the quality of life for all residents of the area. First, it would be extremely irresponsible to allow NPs project to go ahead when there is no consensus on the science. Northern Pulps track record for honesty, for transparency, is a very poor one and it stretches back several decades. During those decades, while they claimed otherwise, their effluent has been poisoning parts of Pictou County. It is difficult, in fact it is impossible, to believe their current claims that this new process will have no negative environmental impact. There are many concerned citizens and scientists who are familiar with the technical details and are adamantly opposed to this proposal. Im sure you have heard from many of them and those concerns must not be brushed aside in order to gamble recklessly on this project. Second, given the complexity of the science and engineering involved in this project, the situation is made even more difficult when the project is only undergoing a Class One assessment rather than the more thorough Class Two or federal assessment. This fast-tracked process raises doubts and alarms rather than encouraging a sense that the consequences are being evaluated with all the careful attention to fine-grained detail that the project requires. Again, the risk of allowing this to go ahead without the greater certainty that a full scale assessment might provide, and thus allowing the fifty years of toxicity to continue, would be reckless and unacceptable. Third, approval of the project is only part of the issue. NP will apparently require at least a year delay of the January 2020 Boat Harbour deadline in order to complete the project and the toxic effluent would presumably continue to flow during that time. The current environmental assessment should thus include consideration of this environmental fact as well since the two are completely interdependent. This part of the project has absolutely nothing to do with risk or uncertainty. Its toxicity is a matter of public record, its effect has been nothing short of disastrous, and it constitutes one of the major examples of environmental racism in Canada. It is unthinkable that this could be approved and permitted. Yet that is precisely what NPs plan entails. There has been far too much damage already and the risk going forward is far too great. Fifty years is enough. Just say no! Name: Email: @rogers.com Address:

Subject: Northern Pulp Environmental Assessment
Date: March 9, 2019 4:57:36 PM

Hello,
I own a property in Pictou County - Braeshore to be precise and I grew up with that pulp mill across the harbour. It seemed like people coped with the situation because it brought jobs to our diminishing part of the province. But after more than 50 years and living with chronic illness and life threatening diseases like cancer, people have run out of patience for a government that appears to be in a conflict of interest with this whole situation. My request is a simple - we need to have a federal environmental assessment completed. The logic points to this as the next step in this process. It is the right thing to do and wouldn't you say that now is the time for the Government of Nova Scotia to finally do what is fair and just for the citizens of Pictou County and its precious environment?

Sincerely,

Attachments: Letter to Margaret Miller Northern Pulp Replacement Effluent Treatment Facility Project.FINAL.pdf

Honourable Margaret Miller

Environmental Assessment Branch
Nova Scotia Environment
P.O. Box 442
Halifax, NS, B3J 2P8

March 9, 2019

Hon Minister Miller,

I am writing in response to the proposal submitted to the Department of Environment regarding the Northern Pulp Replacement Effluent Treatment Facility Project.

My name is I am a resident living in Pictou except for 3.5 years as a resident of Iqaluit and Yellowknife. I come from a fishing family including past and present and today my brothers' fish in the Northumberland Strait for lobster, crab, herring, and scallops. I spent my summers as a youth at Caribou Island and now spend summers at my husband's family cottage at Waterside.

I served as a Town of Pictou citizen representative on the Town of Pictou Ramsay Report Committee The Town of Pictou Organization Study was competed by Richard G. Ramsay Management Consultants Inc. to address the Town of Pictou's fiscal situation and develop a strategy toward a number of areas including residential, business development in the town of Pictou, increased quality and deliver of water services including our watershed and improved Town services and support to tourism, culture and community organizations.

Source: http://pictouproud.com/Portals/18/documents/20.ramsayfinal.pdf

My submission to you will include three topic areas:

1. The watershed for the Town of Pictou and surrounding community of Caribou
2. The proposed burning of sludge at the Northern Pulp site
3. The impact of the effluent dumped into the Northumberland Strait.

First of all I have to say the one month timeline for the public to respond has been a challenging one. I did my best to study this document. It has been a number of emails and follow-up with others for interpretations.

I also believe that the Department of Environment has an enormous task to respond to Northern Pulps Replacement Effluent Treatment Facility Project by March 29. I wish you and your staff

the best in sorting through what is a deep read and with tangled information, vague outcomes, contingency risks, and what I see no contingency plans to address those risks.

Focus 1: The watershed for the Town of Pictou and surrounding community of Caribou

Part of the Town of Pictou Ramsay Report Committee objective was to provide a plan toward improved drinking water services and risk management as it relates to water quality for Town of Pictou residents. Most recently a new water treatment plant was completed and opened in October 2018.

A document prepared for the Province of Nova Scotia, Department of Environment by the Caribou Source Water Protection Committee Members can be found online at https://www.townofpictou.ca/assets/PDFs/Water/Pictou-SWPP-Update-October-2017.pdf

This document states in its introduction that: *"**Water is a provincial resource and regulated by Nova Scotia Environment (NSE) under the Environment Act**. All Municipalities are required to obtain an approval from NSE to withdraw from water sources (i.e. groundwater and surface water) in Nova Scotia. The Town of Pictou (Town) holds water withdrawal approvals for both the Caribou and Pictou well fields and an **Approval to Operate** (Approval) for their water treatment and water distribution system from NSE under the Activities Designation Regulation. **The Approval details the operational conditions for the Town to ensure compliance with the Environment Act.** Included are provisions for the Town to develop a source water protection plan (SWPP)."*

This introduction clearly states that our drinking water source is regulated by the Nova Scotia Environment (NSE) under the Environment Act and that Approval to Operate for our water treatment and water distribution system. It goes on to state that: *"In 2002, Nova Scotia Environment (NSE) introduced its Drinking Water Strategy to ensure clean drinking water for all Nova Scotians. The main goal of a Water Utility is **to provide safe, clean drinking water to its customers**. **Protecting the quality and quantity of the source water is a top priority for utilities as one-step in the multiple barrier strategy developed for the protection of drinking water quality in Nova Scotia***." I interpret this to be the Department of Environment's responsibility and role to Nova Scotia citizens and communities.

The Town of Pictou who is in the business of providing services to its residents and businesses and the Municipality of Pictou County whose residents have private wells in that watershed, all must follow the guidelines/rules outline in the Pictou / Caribou Source Water Protection Plan.

The risks to water quality were identified as transportation, residential development, waste disposal, agriculture, **industrial development**, and recreation and environmental.

The procedures for development of the Pictou / Caribou Source Water Protection Plan are:
1) Form a Source Water Protection Advisory Committee (Committee);
2) Delineate a Source Water Protection Area Boundary;
3) **Identify Potential Contaminants and Assess Risk;**
4) Develop a Source Water Protection Management Plan; and

5) Develop a Monitoring Program to Evaluate the Effectiveness of a Plan.

I will focus on **#3 Identify Potential Contaminants and Assess Risk;**

Almost every activity on the land has the potential to affect the quality of water in a community. The Town of Pictou focuses on the following to protect its watershed:

Acquisition of Land: "*The acquisition of land by the Town gives direct ownership and control of portions of the source water area to the Town. This allows for a high level of protection of a source area due to direct control over the activities that can take place there."(Page 19)*

Best Management Practices (BMP's): "*These standardized and widely accepted practices for activities and products are the most* ***practical and effective means of preventing or reducing contaminants from reaching source water.*** *BMP's have been developed for most activities, which occur in a well field. They can be applied to various aspects of residential development, including septic system and oil tank installation and maintenance, and construction activities. Most aspects of agriculture have operating BMP's in place through a variety of regulatory and market driven processes. Many of these practices are specifically designed to manage specific activities, which may affect water quality. BMP's are also in place for many industrial products, services, and activities related to motorized recreation and transportation.) (Page 19)* For an effluent pipe to go through this watershed and with only one break in that pipe and it will happen, the province of Nova Scotia will have Boat Harbour #2 happen again.

The Town of Pictou recently opened its own $5.8 water treatment plant, which includes a state-of-the-art system that will eliminate the town's ongoing brown water issues, caused by high levels of magnesium and iron, for many years.

The treated effluent pipe is proposed to go through our watershed to Caribou Harbour. How will we know the precautions are being enforced based on the years of cracked pipes and effluent spills with the most and the most recent spill on Oct. 21, 2018? What will happen when that pipeline has a break? There will be a break at some point in this lifespan. This happens in every building, machinery and industry.

Northern Pulp has a failed history of this happening at last date October 21, 2018 only found by local residents, not NP staff or equipment. We have yet to receive a statement from the Province of Nova Scotia releasing three key pieces of information including: 1.the size or cause of the leak in October 2018, 2.the composition of the effluent that leaked and 3.why the pipe break went initially undetected by the pulp and paper firm owned by Paper Excellence. This is very troubling.

With our history, how will we ever trust the water coming out of our taps with the lack of transparency and accountability with effluent in an expanded watershed? Effluent coming through our facets will not have a taste. It is when it shows up in skin conditions, on-going health issues and diagnoses of cancer then it will be noticed and that is too late. There are families, individuals, business that will be impacted. Our water source for drinking, bathing, recreation, restaurants, tourism and basic living services such as food (including our local grocery store Sobeys) cannot operate without a daily, safe water resource. We will be living in a comparison

to on the poem of –The Rime of the Ancient Mariner" by the English poet Samuel Taylor Coleridge of –water, water everywhere and not a drop to drink," only our salt water will be our toxic, effluent watershed.

Do we want a Pictou, Nova Scotia version of Walkerton? With this effluent going through our watershed we will get it. *"The situation in Walkerton, Ontario, in May 2000 is nothing less than a human tragedy. The outbreak of E.coli, which killed seven residents and left 2,300 people sick, was shocking and frightening for the people in the area. For six long months the town's 5,000 residents had to rely on bottled water and the treating of tap water with bleach, with many going to homes of friends and relatives in neighbouring communities to bathe. Six months after the tragedy unfolded, the town still suffered under boil water advisory." Even after the water was declared safe to drink in December of 2000, many people still felt uncomfortable using what comes out of the tap. Their trust and belief in the water system is seriously eroded. The Walkerton tragedy is a serious reminder of what many Canadians take for granted – the value of clean and safe drinking water."*

Source: https://www.peelregion.ca/pw/waterstory/pdf/activities/case-study.pdf

Focus 2: The proposed burning of sludge at the Northern Pulp site

The proposal states: *Emissions during construction are generally related to the generation of dust from earth moving activities and unpaved temporary access roads, and routine combustion gas emissions from construction equipment. Equipment used for construction will generally consist of dump trucks, excavators, wheeled loaders, bulldozers, and other mobile equipment, similar to what may be seen on many other commercial or industrial construction sites. Control measures, such as use of water sprays on roads during dry periods or other dust suppression techniques, will be used as required to reduce the fugitive dust, and routine inspection and maintenance of construction equipment as well as the implementation of a no-idling policy will reduce exhaust fumes. Waste wood may be mulched and spread on access roads. The burning of waste brush/slash material or grubbings will not be permitted. (*Page 85- 5.0 Project Description- DILLON CONSULTING LIMITED)

Sludge Management System

Waste process sludge from primary and secondary treatment (clarifiers) will be sent to a single sludge holding tank located within the AST building….Burning sludge in this manner reduces the potential for methane emissions from the ETF process and partially displaces the use of fossil fuel that would otherwise be burned in the power boilers for energy production. (Page 81- 5.0 Project Description- DILLON CONSULTING LIMITED)

"The "dewatering process" of the sludge from the treatment facility will work well, and there is no need to worry about burning it in the mill's power boiler, even though that boiler has already caused many emissions problems." https://www.halifaxexaminer.ca/province-house/northern-pulps-environmental-documents-missing-mercury-a-pulp-mill-that-never-was-and-oodles-of-contradictions/

Additional information in a link from the above article as reported by the CBC - Northern Pulp flunks air emission tests — again Paul Withers · CBC News · Posted: Sep 19, 2017 6:30 AM AT | Last Updated: September 19, 2017 https://www.cbc.ca/news/canada/nova-scotia/northern-pulp-air-emission-tests-fails-again-1.4295686

"This is the third year in a row emissions from the power boiler at the Northern Pulp mill exceeded the limits set down by the Environment Department. In June, tests recorded particulate emissions of 224 milligrams per reference cubic metre. The boiler permit allows 150 mg/Rm3."

The proposal has toxic sludge being burned on site in a power boiler that is inconsistent with proper disposal of waste.

In the Town of Pictou, we have a Town of Pictou Outdoor Fire By-law that states:

No person shall have an Outdoor Fire except in an Acceptable Fire Pit, Outdoor Furnace, or for which a Fire Permit has been obtained from the Fire Chief, Fire Inspector or his Designate in accordance with Schedule A herein, and in accordance with conditions as follows:

a. no materials, articles or substances shall be burned excepting Seasoned Firewood or charcoal;

b. an Acceptable Fire Pit shall be located in excess of twenty-five (25) feet from any Building, flammable structure, combustible material or property line;

c. notwithstanding 5 (b), a Chimenea may be operated on a wooden deck provided:

i. it is positioned on a CSA approved fire-proof pad that extends at least eighteen (18) inches from where the door is located and eight (8) inches on all other sides;

ii. it is seven (7) feet from the house and three (3) feet from any wooden surface that is not appropriately screened with a CSA approved fire-proof material;

iii. the operation of a Chimenea meets any standards detailed in the operating instructions accompanying the device;

This means we cannot have a fire pit in our back yard unless it meets the bylaw standards of the Town of Pictou. Yet we will be allowed to breathe in toxic waste from a pulp mill across the harbour. Isn't it ironic?

Source: https://www.townofpictou.ca/assets/PDFs/Town-Hall/By-Laws/Outdoor-Fire-By-law-Approved.pdf

Focus 3: The impact of the effluent dumped into the Northumberland Strait.

In the document, ***Canada's Challenges and Opportunities to Address Contaminants in Wastewater Supporting Document 2, Wastewater Treatment Practice and Regulations in Canada and Other Jurisdictions*** – Environment Canada, March 2018, it states on **page 8**, under the header: **1.2 Regulatory structure for wastewater treatment,** the following states:

*–**The primary federal tool to control the wastewater releases is the Fisheries Act**. Within the Fisheries Act, Environment and Climate Change Canada (ECCC) administers the key pollution prevention provisions (subsections 36 (3) to (6)), which **prohibit the deposit of deleterious substances in water frequented by fish, unless authorized by regulations (Environment and Climate Change Canada, 2017a). A deleterious substance may be any substance that degrades or alters water quality such that it could be harmful to fish, fish habitat, or the use of fish by people**. Under the pollution prevention provisions, ECCC administers and **enforces several regulations, such as those governing effluents from pulp and paper mills, metal mining operations, and municipal wastewater.** The Wastewater Systems Effluent Regulations (WSER; SOR/2012-139) establish baseline municipal effluent quality standards for suspended solids (SS), carbonaceous biochemical oxygen-demanding material (CBOD), total residual chlorine, and un-ionized ammonia (NH3), as outlined in Table 1.1. These regulations impose minimum standards for municipal effluent quality nationwide, and are intended to be achievable through secondary wastewater treatment or equivalent."*

This continues with the following information on page 9*: "In addition to the Fisheries Act, the Canadian Environmental Protection Act (CEPA) is also used to prevent and manage risks posed by toxic and harmful substance. This legal framework may contribute to improved wastewater effluents by controlling substances that are otherwise difficult to treat (CCME, 2009). Under CEPA, owners or operators of wastewater treatment facilities that meet reporting requirements are required to report discharges to the National Pollutant Release Inventory (NPRI), which is a publicly accessible inventory of pollutant releases. NPRI tracks releases of several substances associated with municipal wastewater, such as ammonia, chlorine, metals, phosphorus, and greenhouse gases. However, reporting to the NPRI is only mandatory for facilities in which employees work a total of ≥20,000 hours during the calendar year, thresholds for specific substances are met, or total discharges exceed 10 000 m3 /day (Environment and Climate Change Canada Change, 2016). Because only about 200 WWTPs (out of ~3500) across Canada meet these requirements (Holeton et al., 2011), the contaminant releases shown in this database represent only a subset of the total contaminant loads released into the environment from wastewater treatment facilities."*

The Northern Pulp proposal states: *The group also visited two NBSK pulp mills that operate Veolia BAS™ treatment systems (Södra Cell Värö mill in Väröbacka, Sweden and the Södra Cell Mörrum mill in Mörrum, Sweden) in May 2018. Both of these mills successfully manage the BAS™ treatment system to meet applicable regulations and have ocean discharges for their treated effluent. These visits confirmed that the proposed Veolia BAS™ treatment system will provide the required treatment needs for NPNS to meet current and an anticipated future regulations."* (Page 64 - 4.0 Project Justification and Alternatives Considered - - DILLON CONSULTING LIMITED)

–There is an increased project risk due to lack of reliability in disposal: weather conditions, vehicle maintenance/problems, and appropriate staffing redundancy to accommodate volume of discharge. There will be a significant increase in truck traffic, which will increase noise and potentially the risk to public safety." (page 67- DILLON CONSULTING LIMITED).

The report goes on to state: "*Use of a pipeline increases the reliability of disposal as it is not as subject to weather conditions and staffing as trucking. Additional infrastructure may be necessary, including additional pumping and length of pipe, which includes risks of potential failure. NPNS may be required to purchase/lease additional land to construct a pipeline. Additional approvals and studies will be necessary*." (page 67- DILLON CONSULTING LIMITED).

If I read this correctly, then piping effluent through a watershed into a final drop off into prime fishing grounds and for ocean currents to carry it out into the large mass of Northumberland Strait is a better plan? Let's look at some of the materials that will be in that effluent.

The method that's used at Northern Pulp will create chlorinated pollutants such as chloroform, dioxins and furans and other contaminates released include, heavy metals such as mercury, zinc, cadmium chromium, along with organics, alkyl phenols and oxygen depleting nutrients. I will address two of the nine pollutants stated above from this article:

Source: Report shows heavy metals in pulp mill effluent, Cape Breton Post, Published: Nov 07, 2014 at midnight, Updated: Oct 02, 2017 at 11:27 a.m. https://www.capebretonpost.com/news/local/report-shows-heavy-metals-in-pulp-mill-effluent-7486/

Mercury in the food chain:

Source: NORTHERN PULP'S ENVIRONMENTAL DOCUMENTS: MISSING MERCURY, A PULP MILL THAT NEVER WAS, AND OODLES OF CONTRADICTIONS - MARCH 5, 2019 BY JOAN BAXTERhttps://www.halifaxexaminer.ca/province-house/northern-pulps-environmental-documents-missing-mercury-a-pulp-mill-that-never-was-and-oodles-of-contradictions/?fbclid=IwAR1O3kOUAvSC5KFq-pHKBJYEpk1dwa2olmkWOoITHpaaFEDCkH8BYaE-b6o#Missing%20answers,%20missing%20mercury

Source: https://www.canada.ca/en/environment-climate-change/services/pollutants/mercury-environment/health-concerns/food-chain.html

Mercury in the Food Chain: The Government of Canada website states in its introduction to mercury in the food chain that, *–Almost all mercury compounds are toxic and can be dangerous at very low levels in both aquatic and terrestrial ecosystems. Because mercury is a persistent substance, it can build up, or bioaccumulate, in living organisms, inflicting increasing levels of harm on higher order species such as predatory fish and fish eating birds and mammals through a process known as "biomagnification"... "In the environment, particularly lakes, waterways and wetlands, mercury can be converted to a highly toxic, organic compound called methylmercury through biogeochemical interactions. Methylmercury, which is absorbed into the body about six times more easily than inorganic mercury, can migrate through cells which normally form a*

barrier to toxins. It can cross the blood-brain and placental barriers, allowing it to react directly with brain and fetal cells."

"The most important pathway for mercury bioaccumulation is through the food chain, as illustrated in the figure below. In the water, plants and small organisms like plankton take up mercury through passive surface absorption or through food intake. For "autotrophic" organisms (which do not eat other organisms), passive absorption is the only route of exposure. The amount of mercury that results in these species from even a lifetime of passive absorption is not generally harmful to the organism. On the other hand, heterotrophic organisms (animals which eat other life forms) may be exposed to dangerous concentrations via a second route. Methylmercury biomagnifies through the food chain as predators eat other organisms and absorb the contaminants that their food sources contained. Over time, an individual who consumes plants or prey contaminated with methylmercury will acquire levels greater than in either its habitat or its food. ***As a result, top predators acquire greater body burdens of mercury than the fish they consume."*** **The top predator is "We", the human consumer.**

Zinc in the Food Chain:

Source: https://www.lenntech.com/periodic/elements/zn.htm

~~-~~Water is polluted with zinc, due to the presence of large quantities of zinc in the wastewater of industrial plants. This wastewater is not purified satisfactory. One of the consequences is that rivers are depositing zinc-polluted sludge on their banks. Zinc may also increase the acidity of waters.

"Some fish can accumulate zinc in their bodies, when they live in zinc-contaminated waterways. When zinc enters the bodies of these fish it is able to ***bio magnify up the food chain***." As we

humans are many times the final customer on the food chain, zinc impacts our health by, *"Very high levels of zinc can damage the pancreas and disturb the protein metabolism, and cause arteriosclerosis. Extensive exposure to zinc chloride can cause respiratory disorders…Zinc can be a danger to unborn and newborn children. When their mothers have absorbed large concentrations of zinc the children may be exposed to it through blood or milk of their mothers."* **Source:** https://www.lenntech.com/periodic/elements/zn.htm

"Industrial sources or toxic waste sites may cause the zinc amounts in drinking water to reach levels that can cause health problems." **Source:** https://www.lenntech.com/periodic/elements/zn.htm

- https://nsadvocate.org/2019/01/24/matt-dort-on-northern-pulp-effluents-and-the-northumberland-strait-its-about-more-than-meeting-flawed-regulations/

Northern Pulp on under the Human Health Evaluation starting on page 489 states, *"Public and regulatory concerns regarding the potential human health effects of project emissions and treated effluent discharges have been raised throughout the project development period, and it is likely that such health-related concerns will continue to be raised during NSE's EA review process.*

The project has two main sources of emissions/discharges that may result in potential human exposure to project-associated chemicals:

• ***The marine treated effluent diffuser; and,***

• ***Air emissions from the replacement ETF and existing NPNS mill due to future planned co-combustion of sludge with hog fuel in the mill power boiler.***

At this time, effluent chemistry characteristics (including the specific substances present in treated effluent and their anticipated concentrations) ***will not be known with certainty until the project is operational."***

"Will not be known with certainty until the project is operational?" This is totally unacceptable. We the citizens in direct path of air emissions made up on sludge with hog fuel

are to wait until the gases come across the harbour at us and we are diagnosed with cancer that we will find out at that time the new process burning sludge is not good for us?

The government is putting itself in a precarious position to even think of allowing industry to act this out in 2020.

One more point:

On page 34 in the Executive Summary submitted by DILLON CONSULTING in Table E.1.1-1: Summary of the Significance of Project-Related Residual Environmental Effects, the abbreviation of NS = No Significant Residual Environmental Effect Predicted is assigned for each Valued Environmental Component (VEC) with sub headers of Project Phase Accidents (Malfunctions, and Unplanned Events), Project Overall, Construction, Operation and Maintenance.

How can a project of this magnitude to be completed and up and running by January 31, 2020 not have at least a minimal of two of the following risks?

S = Significant Residual Environmental Effect Predicted.

L = Residual Environmental Effect is Likely to Occur.

U = Residual Environmental Effect is Unlikely to Occur.

P = Positive Residual Environmental Effect Predicted.

And where in this report is a contingency plan? This proposal is best case scenario with worst case results for those of us in its path.

There is just no way can this project be trusted by any of us who will be directly impacted by this project. There is just no trust with this company.

My Recommendation

I urge the Hon. Margaret Miller to reject the Northern Pulp Replacement Effluent Treatment Facility Project. Everything I wrote on the last 10 pages state why this project must be cancelled for the sake of drinking water, health of residents, health of our food supply, economic health and for all of us Northern Nova Scotia, Prince Edward Island and New Brunswick. The risks as I outline are significant adverse effects that cannot be mitigated.

This proposal in its presented format will forever impact the drinking water for the Town of Pictou and Municipality of Pictou County residents in this area. This proposal will forever impact the fishing industry in this region and beyond. This proposal and the results will come with more health issues, respiratory illnesses and cancer rates in addition to a spoiled reputation of Canada's Ocean Playground. This proposal will impact our province, the province of Prince Edward Island and New Brunswick. It took only one mad cow to stop an industry in its tracks.

This is not an ~~"if~~" statement. This is a ~~"w~~hen" statement. History will repeat itself.

There is a Plan B for Nova Scotia, including the forestry industry. Today there has never been such a demand for wood and its products. There is a very bright future ahead for the forestry

industry that is different from ripping under age trees from the ground and mincing them into pulp for paper and toilet paper. We just change our natural resource, grow hemp for those products and follow the Leahy Report.

We need to address climate change and work toward meeting those targets. We must reduce our environmental impact with more sustainable industries and a 2020+ vision.

As a taxpayer of this province, I will be paying for the decisions that will be made over the next month for many years. I want to pay taxes on a Plan B that gives us a healthier province and a bottom line positive impact to our economy, forestry, fishing, tourism, business communities, and for all residents in this community and beyond. We just need to get to work on Plan B.

Thank you

Subject: Proposed Project Comments
Date: March 9, 2019 5:33:47 PM

Project: replacement_effluent_treatment_facility_project Comments: The future of our air and water are of the utmost importance. It is far more important than profits for an already wealthy foreign conglomerate. The wealthy family who owns a litany of companies, including Paper Excellence parent company of Northern Pulp has been convicted of illegal logging in China, Cambodia, and Indonesia. Why should we trust them? I can guarantee they dont care at all for the future of Nova Scotias forests or people. I have no faith or trust in Northern Pulp after decades of lying and spewing their noxious chemicals into my hometowns air. I do not support the pipeline into the Northumberland Strait. I am strongly opposed to high temperature waters which I believe will also be polluted with chemicals entering the strait. I am certain that the impact on the ecology of the area near the outfall, and further removed, will be significant. Rising temperatures in ocean waters are already a serious concern with climate change. The last thing we need to do is further contribute to the temperature rise. I understand there is concern for jobs, especially in rural Nova Scotia. However, NS Governments most recent tweet March 9, 2019 states that the unemployment rate is at its lowest since modern surveys began in 1976. It is also time for our rural economies and forestry industry to diversify. With some effort and innovation, I think there are great potential opportunities in both industries. Whatever happens, it is extremely important that the province keeps their promise and closes Boat Harbour by January 2020. Name: Email: @gmail.com

Subject: Northern Pulp's Replacement Effluent Treatment Facility Project
Date: March 9, 2019 5:35:26 PM

---

ea@novascotia.ca

minister.environment@novascotia.ca

Dear Minister Miller,

I respectfully request that you reject Northern Pulp's effluent treatment replacement proposal on the grounds that it will have a greatly negative impact on an already fragile ecosystem- the Northumberland Straight.

I grew up in Pictou and still clearly remember when the mill began operation. I was 11 years old, gagging at the rotten egg stench as I walked to school with my friends. We all wondered when we could breathe fresh air again. I remember being told that I would soon get used to the smell, that it meant jobs for Pictou County, that it was stinky but safe. I remember when we were no longer able to take the little ferry to Pictou Landing to swim off the pier with the indigenous children, or at any of our usual beaches, because the water had become "contaminated". My family would only swim or fish in waters outside of
Pictou Harbour after that.

After high school I moved to Halifax for study, became a Registered Nurse and worked in health care . As I worked and learned about the determinants of health I came to realize the risks posed by environmental pollution. Safe water, clean air and healthy workplaces are vital for healthy communities. It became obvious then that the health of the populations of Pictou, Pictou Landing First Nation and much of Pictou County were being sacrificed for some jobs at a massively polluting pulp mill.

Many in my large extended family reside throughout the Pictou County and I still spend considerable time there. I shop, eat out and attend entertainment events in Pictou. The Capital of Pictou County, it is a town steeped in a rich cultural heritage as the birthplace of New Scotland. Each summer folks from throughout the county, the province and beyond gather to celebrate the labours of local fishermen at the Pictou Lobster Carnival. The deCoste Performing Arts Centre hosts cultural and musical events throughout the year and is a tourism hub for visitors arriving by car and by boat at the nearby marina. I sometimes sail in the deep waters of Pictou Harbour out to Pictou Island. I camp at the local provincial park, Caribou-Monroe's Island, and take leisurely walks around that unspoilt natural preserve. I visit and stay near the Caribou Island Lighthouse, and walk on the mudflats at low tide. I swim and kayak along that shore and share the unique tranquility with shorebirds and seals. I wish more people could have the opportunity to share and respect the beauty and peacefulness of the Northumberland Straight.

I believe the tourism industry in Pictou County has great potential, but the smelly polluting eyesore directly across the harbour from downtown Pictou is definitely a detractor. Visitors are often put off by the site and/or smell and choose to spend time and have their meals elsewhere. The locals hope for change.

I am keenly aware that Northern Pulp provides employment opportunities to this community, but at what cost now and in the future? I understand the necessity of jobs to the survival of a community. Two of my brothers worked at the mill; the elder as an engineer in the and the younger as a tradesman in the The elder, now in his late , worked there when the mill was newish and well maintained. The younger worked there through new management, shortcuts in maintenance, and an ever increasing demand to produce more regardless of the capacity the mill was designed to manage.
My father, brother, and other relatives were/ still do make a living from fishing lobster and other seafood off the coast of Pictou County. These jobs provide food and income, and are also part of the culture and heritage of Nova Scotia.

Based on Northern Pulp's well documented track record I do not believe they are good corporate citizens. The preservation of this area is not their priority, but rather their own profit for investors abroad. I am very concerned about the current plan for the effluent pipe. I share in the fear that Pictou's watershed area will be placed at risk from pipe leakages and that the coastal waters around Pictou County will become devoid of marine life, unsafe for human recreation, and a vital fishing industry will be lost.

I stand with the First Nations peoples of Pictou Landing in opposing this plan and agree that many years of environmental racism must end.

I encourage you to stand for the preservation of a heathy environment in and around Pictou County, for the people and for the aquatic life.

Sincerely,

Sent from my iPad

Environmental Assessment Branch
Nova Scotia Environment
P.O. Box 442

Email: EA@novascotia.ca

Dear Ms. Miller:

Re: Northern Pulp Nova Scotia - Environmental Assessment Registration Document- Replacement Effluent Treatment Facility

In Addition to my Submission on March 6th, I would like to add this comparison of the Northern Pulp Mill that is proposing to build an AST system to a mill in British Columbia that is using an AST system and show the major difference in their receiving waters. I have also added in the attached document the scollop buffer zone that the fishermen must abide by within their conditions for scollop fishing. This shows the difference in how Northern Pulp shows the buffer zone in their EA versus how DFO has set it in according to the Fisheries Act. Also in the document is a image of the present day ice report showing the gulfs ice conditions and how the ice affects the strait.

After looking through my document, I hope you understand why there are many issues of great concern to me in Northern Pulps EA submission. These issues need more review and information to insure the heath and safety for both the people of Nova Scotia and the Northumberland Strait to which we fish and share with surrounding Provinces. I am asking that you, as Minister for Nova Scotia Environment, order an Environmental Assessment Report of Northern Pulp's proposed effluent treatment facility.

Thank You

Lobster Fisher,

Water depths surrounding proposed pipe location & outfall

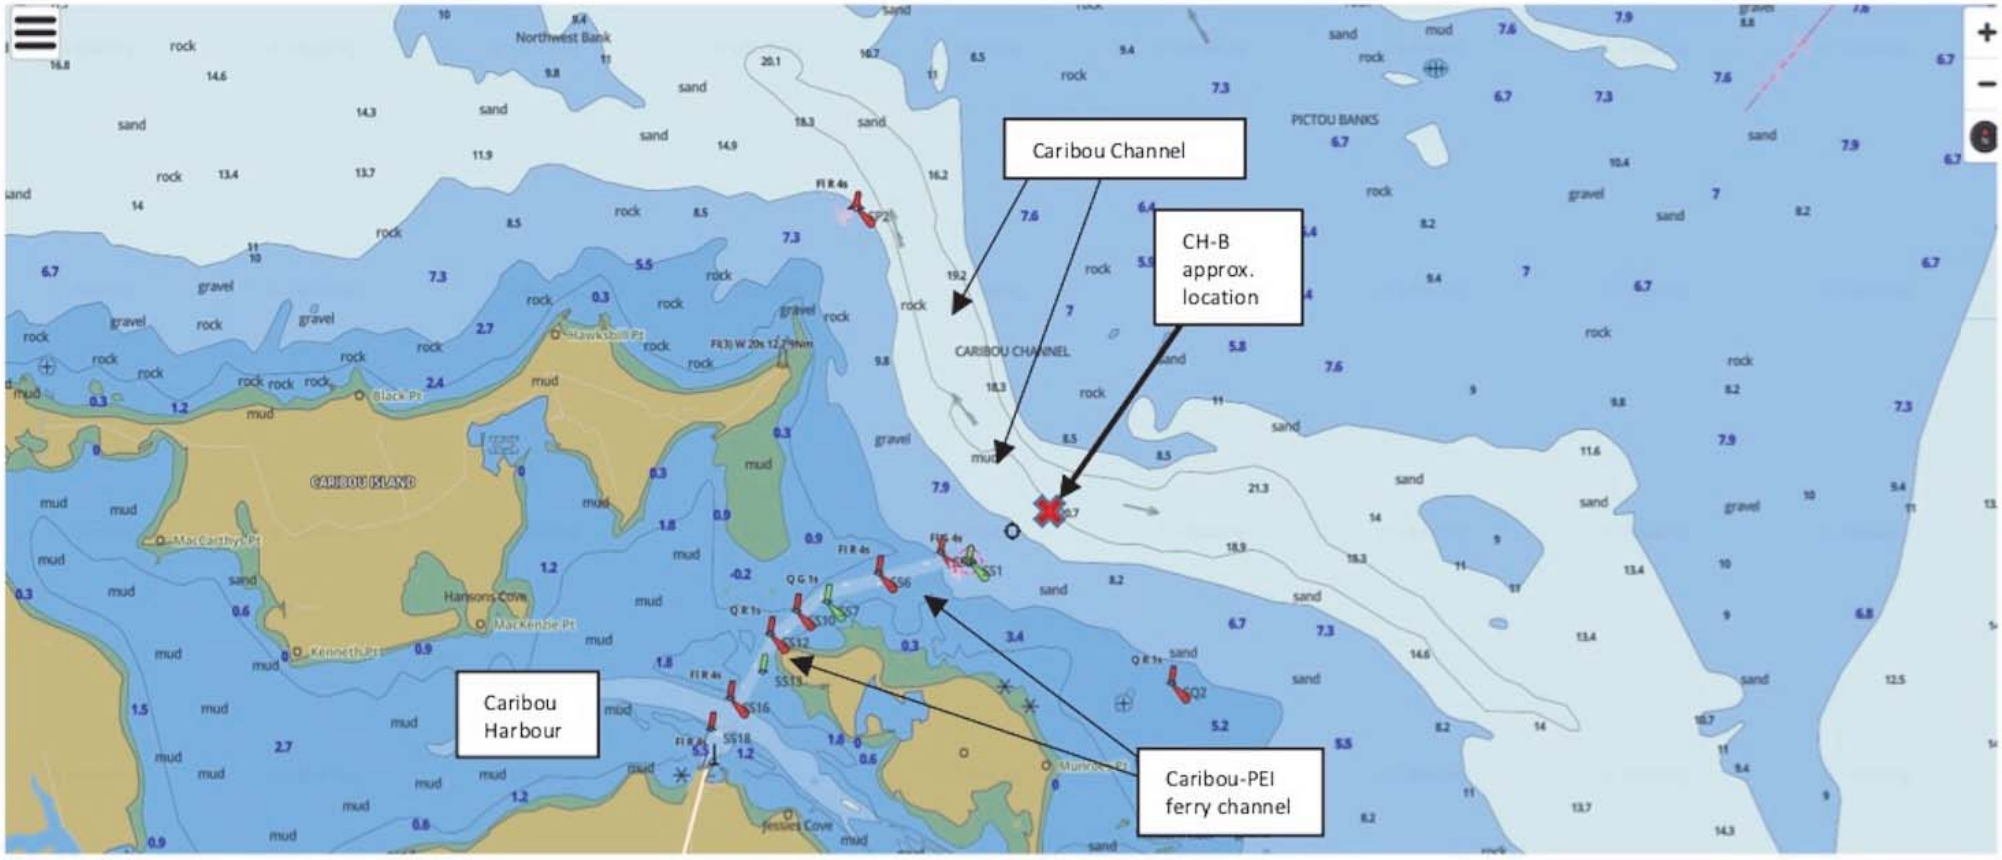

Chart of Caribou Channel and surrounding area

Northern Pulp's proposed outfall at point CH-B in the Caribou Channel is to be placed in a relatively small area with a depth of 20 metres. As this chart illustrates, the area becomes significantly shallower within a short distance. Depths are more typically between <1 to < 8 metres in most of the surrounding Caribou Harbour and Pictou Banks area.

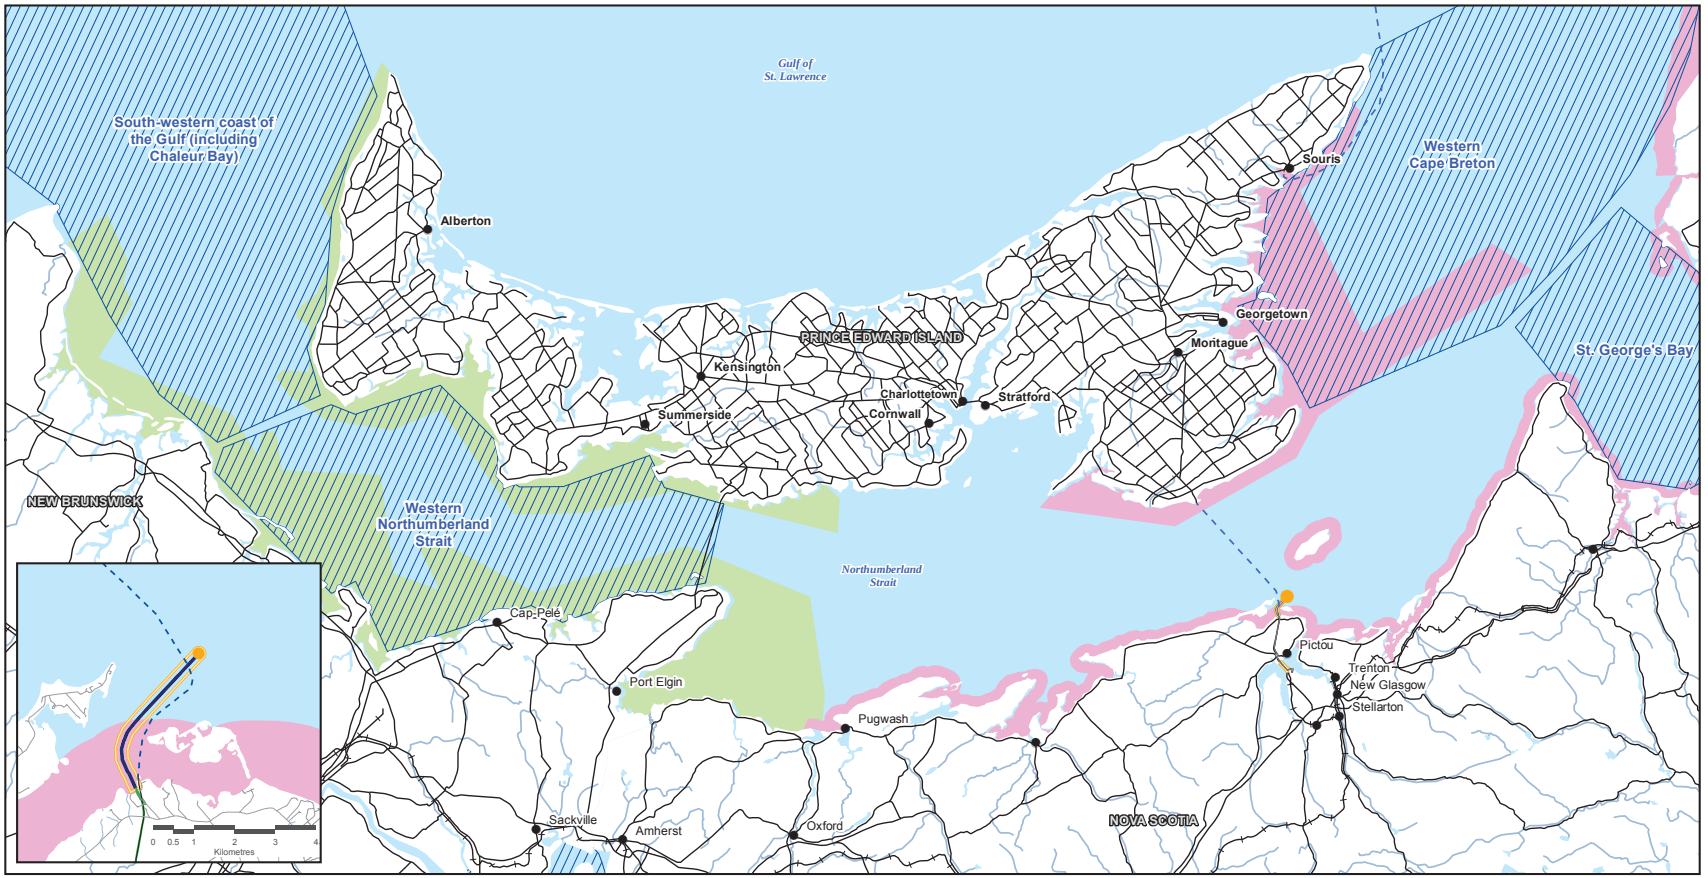
Scallop Buffer Zones as depicted in Northern Pulp's EA



8.12.2.7 special areas 382

Scallop Buffer Zones SFA 22 and 24 are part of a system of Scallop Buffer Zones in SFA 21, 22, and 24 that covers a total area of 5,835 km^2 (DFO 2017). **Scallop Buffer Zones were established to protect juvenile American lobster as they are known to contain lobster nursery habitat** (DFO 2017). Scallop Buffer Zone SFA 22 is in the western Northumberland Strait, approximately 85 km to the west of the marine PFA. Scallop Buffer Zone SFA 24 is in the eastern Northumberland Strait and the effluent pipeline will cross through the Scallop Buffer Zone SFA 24 close to shore (**Figure 8.12-10**) in Caribou Harbour near Jessies Cove. The location of the outfall is outside this buffer zone.

Outfall and pipeline fall within Scallop Buffer Zone which protects juvenile lobster habitat

In the text accompanying image 8.12.2.7, special areas 382, which includes this inset map, Northern Pulp states, “The location of the outfall is outside this [scallop] buffer zone.”

The scallop buffer zone for this area is defined in Fishing Season Conditions 2018 Document DFO-0000471625. Scallop Condition 7 reads**:**

> *No person shall fish for scallops in that portion of scallop fishing area 24 in those waters adjacent to the Province of Nova Scotia within one [1] nautical mile from the nearest point of land in the counties of Cumberland, Colchester, Pictou, including Pictou Island in the Northumberland Strait, and Antigonish.*

The map provided by Northern Pulp does not include the scallop buffer zone around Munroe’s Island and Caribou Island (the white shorelines that are missing pink outlines.) This is clear on the inset map. The omission of the buffer zones in these areas makes it appear that the outfall location (orange dot) is farther from the buffer zone than it actually is.[1]

Measuring one nautical mile (1.852 km) from every point of land in the area, as defined in Scallop Condition 7, **the proposed outfall location would fall within the buffer zone, not outside it as Northern Pulp states**. Although Northern Pulp has not provided precise lat-long co-ordinates for the outfall, its location on Northern Pulp's map and the description that it is situated in one of the few deep areas would place it within the scallop buffer zone.

Northern Pulp also states “the effluent pipeline will cross through the scallop buffer zone SFA 24 close to shore.”

The distance from shore that the effluent pipeline would cross through the scallop buffer zone as represented on Northern Pulp’s map is 1.85 kilometers (1 nautical mile.) Because the term “close to shore” is vague, it is important to note the actual distance is almost 2 kilometers.

However, an accurate representation of the scallop buffer zone would show that **the entire 4.1km pipeline would run through the scallop buffer zone.**

In the list of marine refuges, Fisheries and Oceans Canada describes the conservation objective for Scallop Buffer Zones (SFA 21, 22, 24) as "to protect juvenile lobster habitat."[2]

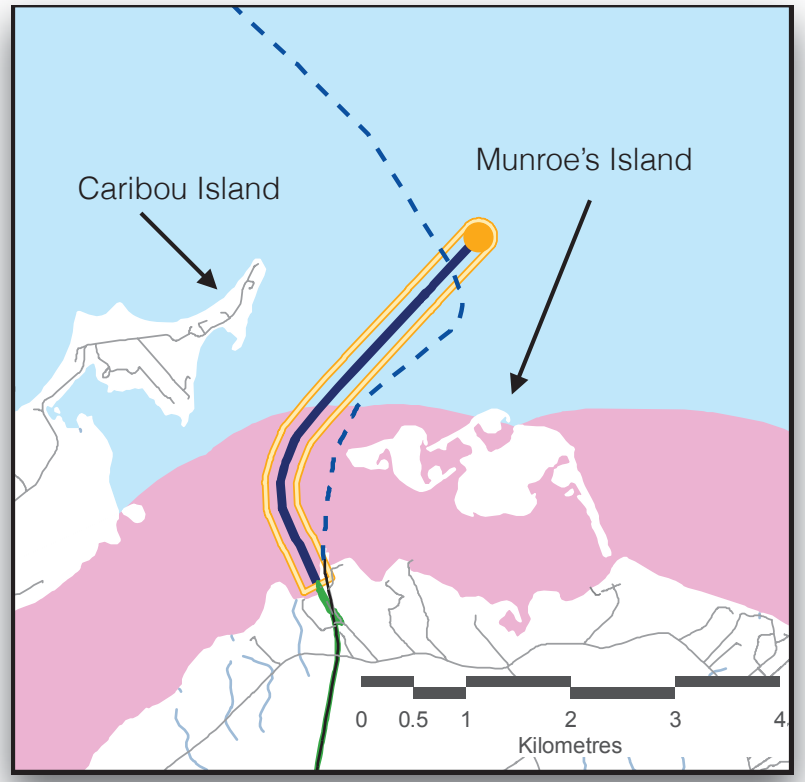
They further state:
"The following ecological components of interest are conserved through the prohibitions.
Species of regional importance: juvenile American lobster

- **Why it is important**: American lobster is a commercially important species.

Habitat that is important to biodiversity conservation: American lobster nursery habitat

- **Why it is important**: American lobster nursery habitat is important for the life-cycle of the species.

In addition to prohibition on scallop dragging, the section on prohibitions also notes:
"No other human activities that take place in this area are incompatible with the conservation of the ecological components of interest.”



The Environmental Context for the scallop buffer zone notes, "**These closures offer protection to other important species and habitats** in the southern Gulf of St. Lawrence. For example, SFA 22 contains the last remaining area in which the winter skate (a population under the endangered designation by COSEWIC) is found during the summer. It also includes a unique population of lady crab (suspected to be endemic to the region), and the rock crab (an important prey for several species and a commercial species).”

We note that fishers in the Caribou area are aware that the immediate area of the proposed outfall and surrounding areas contain a population of rock crab and juvenile rock crab.

[1] We have spoken to DFO. They confirm that the conditions of the license are the conditions enforced under the Fisheries Act. DFO recognizes that there are errors on the on-line map and they are in the process of making corrections.

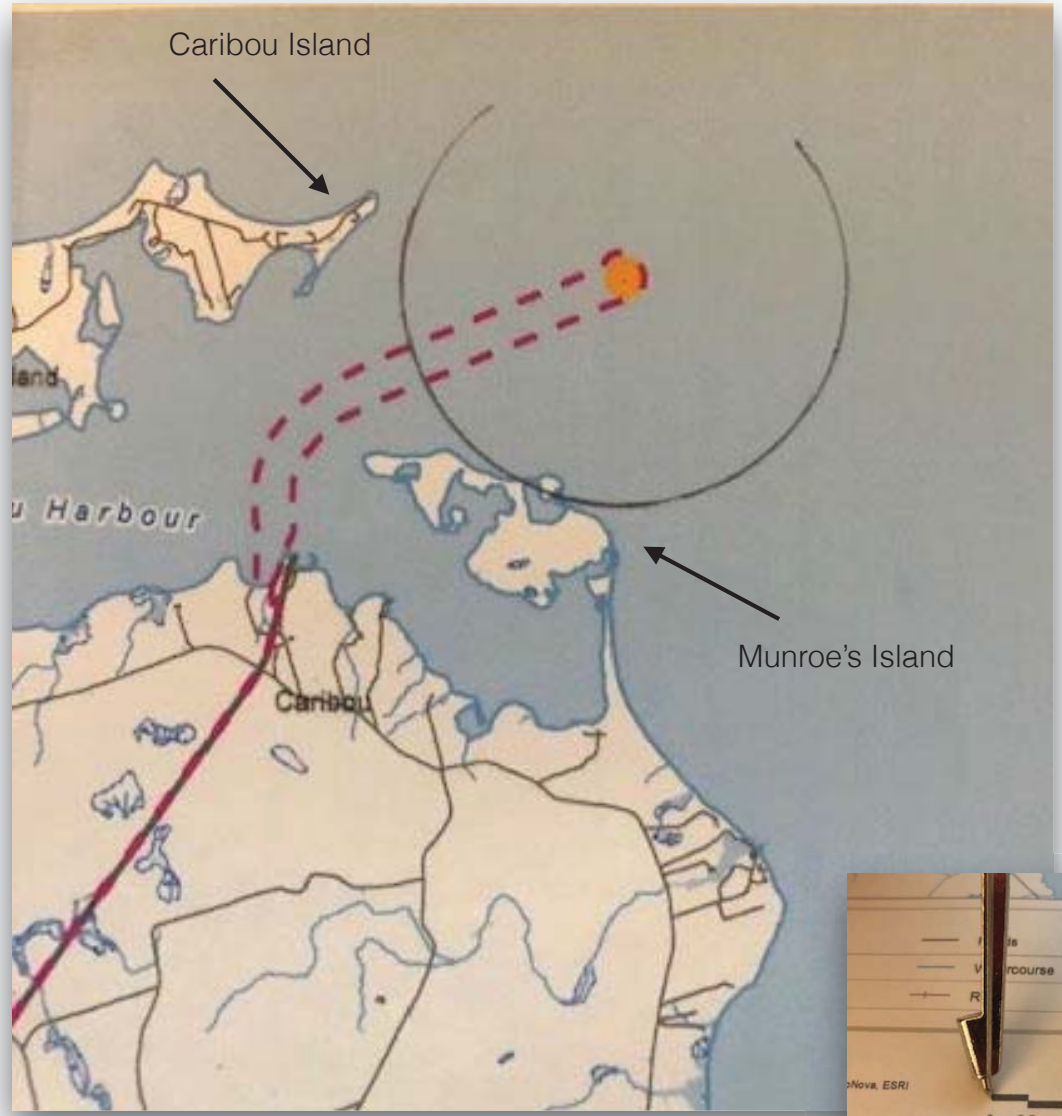
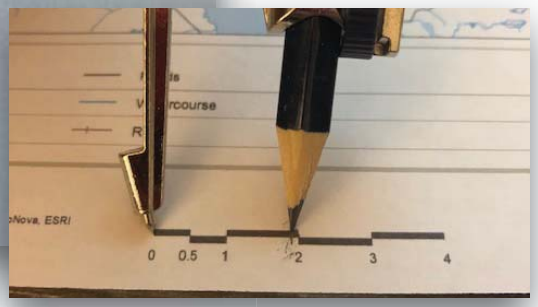
Northern Pulp proposed outfall with Scallop Buffer Zone



Measuring one nautical mile (1.852 km) from every point of land in the area, as defined in Scallop Condition 7, the proposed outfall location would fall within the buffer zone, not outside it as Northern Pulp states. Although Northern Pulp has not provided precise lat-long co-ordinates for the outfall, its location on Northern Pulp's map and the description that it is situated in one of the few deep areas would place it within the scallop buffer zone.



1.852 km = 1 nautical mile

REGISTRATION(S) AND/OR FISHING LICENCE(S) - 2018

This document authorizes the registration card holder and/or licence holder to engage in fishing and related activities on the Atlantic coast of Canada subject to the provisions of the Fisheries Act, the Species at Risk Act and the Regulations made thereunder.

This licence and/or registration is issued under the authority Minister of Fisheries and Oceans Canada.

LICENCE HOLDER

[redacted]

FIN [redacted]

ISSUANCE DATE: October 20, 2018

ISSUING REGION: GULF

Licence No. [redacted]

Species SCALLOP, SEA

Homeport CARIBOU/FERRY WHARF

Operator [redacted]

Vessel [redacted] NAME: [redacted] LOA: [redacted]

2018 LICENCE CONDITIONS
VALID FOR FISHING SCALLOP
IN SCALLOP FISHING AREA 24

This licence confers on the licence holder/operator, subject to the Fisheries Act and Regulations made thereunder, the authority to fish under the conditions set out below:

1. FISHING AREA

1.1 These licence conditions are valid for fishing Scallop in Scallop Fishing Area 24.

1.2 It is prohibited to fish in the portions of scallop fishing area 24 as described in Annex B -Definitions of the Scallop Buffer Zones.

2. FISHING GEAR

2.1 These licence conditions authorize the use of the following gear: Drag(1)

2.2 While at sea during the daily closed times, all scallop gear must remain on board the vessel.

2.3 The maximum cumulative width of scallop drag buckets must not exceed 5.08 meters (outside measurement). The measurements must be taken on the outside of each bucket.

2.4 All rings used in the scallop drag must have unobstructed circular openings, the inside diameter of which shall not be less than 82.6 mm with the exception of the first row of rings attached to the bucket frame where the inside diameter of all rings shall not be less than 76.2 mm. The use of rings or solid blocking in the end of the drag bucket is authorized. When using chain sweeps, the mesh used must create an opening equal in size to the 82.6 mm rings.

Warmer Water Poses Threat to Gulf of St. Lawrence

TELEGRAPH JOURNAL

Warmer waters pose threat to province's seafood stocks

JACOB LORINC TIMES & TRANSCRIPT

Sept. 28, 2018

A University of Washington study shows the Gulf of St. Lawrence is losing oxygen faster than almost anywhere else in the world's oceans, threatening a range of species vital to the Maritime economy.

Published last week, the study found the decline to be directly connected to climate change, as increased carbon dioxide from urbanization and industry seeps into ocean currents and flows into freshwater regions.

Study leader Mariona Claret said water from the Gulf Stream, which flows northwards along the eastern coast of North America, is filtering into the St. Lawrence Seaway as the Labrador Current – which flows southwards toward the Maritime region and typically blocks the entrance of gulf stream waters – weakens.

In turn, temperatures rise in deep-water areas of the Gulf of St. Lawrence, producing a decline in oxygen levels.

"The change is being amplified in this area because now what's happening is that the Gulf Stream is blocking the Labrador currer from transporting oxygen-rich waters toward the Grand Banks," Claret explains."Warmer water then enters the Gulf which lowers the oxygen level."

Katja Fennel, a professor of oceanography at Dalhousie Universit says the lower oxygen levels are unsuitable for species such as Atlantic wolffish, Atlantic salmon, Atlantic cod, and snow crabs, who dwell in lower levels of the gulf.

"Some species are better at withstanding lower oxygen levels tha others," she says. "But if these oxygen levels continue, Atlantic co for example, will not be able to thrive because of oxygen levels."

Some of these species are crucial to New Brunswick fisheries. According to Fisheries and Oceans Canada, snow crab, is the second-most valuable commercial fishery in Atlantic Canada.

"The crabs are also the least resistant to low oxygen levels, though, which poses a problem for them in areas of the gulf," sa Fennel.

She notes that changing oxygen levels may lead snow crabs to migrate to other areas in the gulf, forcing commercial fishing zon to be redrawn.

"It could have an impact for fishing, yes, but it's difficult to say where they would relocate and how that would be accommodate for fishing," Fennel says.

Fennel says snow crab numbers dipped in 2012 as a result of warming temperatures, but notes that the changes in temperatu won't always be consistent.

"There's a lot of variability in the ocean, so some years oxygen wi be low and some years it will be high. But we do know that, on average, the levels are declining, which in time-scales of three to four decades will pose problems for the fish."

Declining oxygen levels in the gulf have been monitored for years Fisheries and Oceans Canada has tracked rising temperatures in the St. Lawrence area since 1920, and began following oxygen levels in 1960.

In 2005, the department reported that oxygen levels declined dramatically, but could not specify the cause.

"What we show is that much of this change is related to climate change, and is associated with the carbon emissions that are released into the atmosphere," says Claret.

"This is happening now," says Fennel. "I can't tell you whether it's going to be in five or seven years when something really bad happens, but we're talking about within our lifetime."

Subject: Northern Pulp"s Replacement Effluent Treatment Facility Project
Date: March 9, 2019 5:45:06 PM
Attachments: EA Letter.docx

Good afternoon,

Attached is my letter requesting Minister Miller to reject Northern Pulp's Replacement Effluent Treatment Facility Project.

Thank you,

March 9th, 2019

The Hon. Margaret Miller
Minister of Environment

Minister Miller:

I am writing in relation to Northern Pulp's Replacement Effluent Treatment Facility Project.

My name is I grew up in the small community of Caribou River on the Sunrise Trail along the beautiful Northumberland Strait.

I am the daughter of a third-generation fisherman, and great granddaughter of , a former Pictou County councilor, Pictou Landing resident and land owner. My great grandfather's property near Boat Harbour was expropriated by the Nova Scotia government for use by Scott Paper Company in the 1960s.

I am currently residing in Amherst, and work seasonally for Tourism Nova Scotia as a travel counsellor at the Visitor Information Centre at the Nova Scotia/New Brunswick border.

I wrote an original thesis, titled, "Voices of the North Shore: The Lobster Fishery of Pictou County."

I am requesting that you reject this proposal by Northern Pulp based on the fact that there is simply not enough evidence to prove there will not be irreparable adverse and environmental effects. I also do not believe that this EA process has been fair. Northern Pulp did not hold public consultations on the Caribou Harbour effluent pipe outfall site plan, as they previously had with their initial Pictou Harbour effluent pipe outfall site plan. It is also unfair to expect the general public to be able to sift through and comprehend thousands of pages of documents and appendices that were included in Northern Pulp's Environmental Assessment Registration Document in a thirty-day period. In the event that you do not reject this proposal, I ask that you require an Environmental Assessment Report, or defer the proposal to the CEAA for federal review.

I work on the frontlines of the 2.7 billion-dollar tourism industry in Nova Scotia, and it is my job to help our visitors make informed decisions about where to visit in our beautiful province. Having grown up on the Sunrise Trail, I always suggest it as a scenic alternative to the TransCanada Highway, especially for those travelling towards Cape Breton Island. Visitors can experience the sweeping seaside farmland, lush forests, small fishing communities, and the well renowned sandy beaches and warm swimming waters of the Northumberland Strait along this secondary route. If Northern Pulp is permitted to place an effluent pipeline in Caribou Harbour, near one of the most popular provincial park campgrounds and beaches along the Northumberland Shore, any detrimental effects from the effluent would be felt immediately by tourism operators all along the Northumberland Strait. Visitors already comment on the 'stink'

that hangs over the Town of Pictou from Northern Pulp, and it would be difficult to confidently tell visitors that it is safe to swim in the waters of the Northumberland Strait with the lack of information that has been given about the makeup of the effluent. Northern Pulp's Environmental Assessment Document states, "At this time, effluent chemistry characteristics (including the specific substances present in treated effluent and their anticipated concentration) will not be known with certainty until the project is operational."[1] This is unacceptable. Allowing a pulp mill to potentially dump effluent in to a body of water without knowing the composition of said effluent is outrageous and wholly irresponsible, on the part of the mill as well as the provincial and federal governments. If Nova Scotia's tourism industry suffers as a result of this project, it will falter and generate less revenue for the province. As an industry that is striving for $4 billion in revenue by 2024, tourism, and the province, cannot afford to support this project.

The pipeline also has the potential to cause mass devastation, not only to lobsters, but to other species within the environment as well. Pelagic species of fish and bivalves (such as mussels, scallops and oysters) would be contaminated or killed off by the effluent, or from the extreme temperature of the effluent, as noted in Table 5.2-1 found on page 46 of Northern Pulp's Environmental Assessment Registration Document .[2] The study, "Detecting p53 family proteins in haemocytic leukemia cells of Mytilus edulis from Pictou Harbour, Nova Scotia, Canada," by S. St-Jean et al. from 2005, provides a detailed study on the impact of the environment on blue mussels in fourteen various sampling sites chosen in the Pictou Harbour and harbour mouth. The researchers found that each set of healthy mussels placed in all fourteen sites developed leukemia cells and contained various other carcinogens.[3]

I would also like to note that in Appendix O-R, "A Summary of the Scientific Literature Related to the Effect of Bleached Kraft Mill Effluent on the American Lobster (Homarus americanus)," prepared for Dillon Consulting Ltd. by of Mount Allison University, focuses on lobster exposure studies completed in the 1960s. Clark notes, "However, due to the range of individual lobster susceptibility, and the considerable change in chemical composition of today's treated BKME, it is recommended that lethality testing, along with additional exposure tests, be completed with today's treated BKME to determine the impact that treated BKME will have on American lobsters."[4] I would also like to draw attention to the fact that had included documents by in his references. However, he omitted one document by , titled, "Bleached kraft mill effluent near Pictou, N.S. and its effect on the marine flora

[1] Dillon Consulting Ltd., *Environmental Assessment Registration Document: Replacement Effluent Treatment Facility*. Submitted January 31, 2019.
[2] Dillion Consulting Ltd., *Environmental Assessment Registration Document …,* 2019.
[3] St-Jean, S., Stephens, R., Courtenay, S. and C. Reinisch, *Detecting p53 family proteins in haemocytic leukemia cells of Mytilus edulis from Pictou Harbour, Nova Scotia, Canada.* Canadian Journal of Fisheries and Aquatic Sciences, 62, (2005): 2055- 2066.
[4] Dillion Consulting Ltd., *Registration Document Appendix O-R*. Submitted January 31, 2019.

and fauna with a note on the Pictou Co. lobster landings."[5] I would suggest this document be reviewed as well by the Department of Environment.

I do encourage you to consider what was shared in all the letters sent for review by the public during this thirty day input period. Many have worked very hard to convey their concerns and expect their government to take everything shared in to consideration. We must all take responsibility for the legacy we are leaving behind. I believe that there would be devastating adverse effects if an effluent pipe is allowed to enter the Northumberland Strait. One tainted lobster is all it takes to destroy the seafood industry of the Atlantic provinces. We must also put an end to the environmental racism that has plagued Pictou Landing First Nation for over five decades. It is unfair to ask them for an extension to the use of Boat Harbour. We must stand with PLFN now as they work towards remediating Boat Harbour.

"Beyond its economic functions, a healthy marine ecosystem is an integral support for local culture and identity and for the quality of life in adjacent communities."[6] Pictou County is much more than the Northern Pulp mill.

Regards,

---

Subject: In support of Northern Pulp"s EA application
Date: March 9, 2019 6:00:52 PM

I am writing in support of the Environmental Assessment application submitted by Northern Pulp for its new treatment facility.

A lot has been said about Northern Pulp and its impact on the local community. I stand in agreement with many, including Unifor, that Boat Harbour must close and be cleaned up to respect Pictou Landing First Nations people and their land. I also know there are many positives about having 300 good-paying jobs in Pictou, supporting thousands more across Nova Scotia, particularly in rural communities.

The Nova Scotia Environment Act is an essential piece of legislation designed to protect our shared environment and guide our economic development. The Act rightly spells out its purpose through a set of principles for sustainable development that should guide its application, including:

------> The linkage between economic and environmental issues, recognizing that long-term economic prosperity depends upon sound environmental management and that effective environmental protection depends on a strong economy.

In this situation, science should determine the best path forward. Nova Scotia, along with the rest of Canada, has among the highest global standards for environmental stewardship in the forestry sector.

The job of government and every person we elect to represent us in government is to find the best way forward when there are many competing and sometimes opposing interests. Communities across Canada manage to find a fair balance where good mill jobs coexist with a prosperous fishing industry and thriving communities.

We can and must find this balance for Pictou. There is a lot at stake: jobs, the environment, and respect for First Nations. We can and must find a solution that supports all three.

Thank you.

Subject: Northern Pulp"s Replacement Effluent Treatment Facility Project
Date: March 9, 2019 6:35:34 PM
Attachments: Letter to the NS Environment Minister.pdf

To Whom it May Concern,

My name is and I am writing in relation to Northern Pulp's Replacement Effluent Treatment Facility Project. I live in Londonderry . I have salt water in my blood. I am a descendant of New England planters, Acadians and Mi'kmaq; of coal miners, fishermen and lumberjacks. My ancestors have lived in Amherst, Springhill, Parrsboro, Cape Breton, Antigonish, Scot's Bay, Pugwash, and Prince Edward Island. For hundreds of years my relations have relied on the natural resources of this province for their livelihoods. If they were here today, they would be ashamed with what is being proposed by Northern Pulp.

My grandmother grew up in Amherst and spent her entire life in and out of the waters of the Northumberland Straight. My father and aunt spent their childhood summers on the beaches. my grandfather bought a small cottage in Linden, directly on the shore, and my siblings and I spent every summer of our childhoods on the beach. And now my son does. And my unborn baby will. . We are the experts of our little strip of shoreline.

Every year we see where the winter surf has pounded boulders into new positions. We watch erosion take its toll on the clay hills. We know the tides. We know when there will be an abundance of seaweed, when the water will be murky, or when the water will be calm and clear. We know when the jellyfish come and for how long they will stay. We watch eagles, seagulls, cormorants, sandpipers and gannets. We see pilot whales, dolphins, small sharks, and schools of fish. We watch the salt ships come and go from Pugwash and fishing boats checking their traps. We have seen the decline of crabs. We pick up litter. We soak up salt. We are the experts. Our hearts are in the Straight and the salt is in our blood. If effluent is pumped into the Straight, what will happen to our little piece of shoreline?

In table 4.2-4 on page 31, Northern Pulp states that a key consideration in locating their Marine Outfall Location is to "develop a solution that does not affect Boat Harbour in the future tidal state…" In this scenario, Northern Pulp is not taking responsibility for anything outside of the Marine Outfall Location. Based on common sense and knowledge of tidal waters, we all know that the effluent cannot be contained within this location. Due to the nature of marine environments being constantly in flux, it is safe to say that the effluent will reach all areas of the straight and beyond. The exact impacts on marine life and coastal areas are impossible to predict because they cannot be studied until they are happening, in which case it will be too late. But again, common sense tells us that any foreign substance that is chemically treated will have adverse effects on the environment. This is an irresponsible, "deal with it later" approach on behalf of Northern Pulp.

My family and I work in forestry across the country. I've been a tree planter, a silviculture manager, and a harvest block planner for various companies. In Nova Scotia, I have worked for Northern Pulp and Irving. I've kept my ear to the ground, listened to, and learned from the professionals. I understand this industry and I understand what closing the mill would do to our local economy. I know that a closure will affect both mill employees and contractors, my

family included. There will be an economic impact that ripples throughout the province for some time. But economies rise and fall all the time. Money comes and goes. Alternatively, we have one planet, one ecosystem. Ask yourself what is more important. Pumping effluent into the straight is absolutely backwards, idiotic and irreversible. I ask you to please do whatever is in your power as a representative and advocate for Nova Scotia's environment to do just that: represent and advocate for our environment. We cannot allow an effluent pipe into the Northumberland Straight.

In terms of the Project Justification and Alternatives (section 4.0), all I have to say is it is shameful enough that the Lahey review suggests the continued application of glyphosate on harvest blocks in Nova Scotia. Now Northern Pulp wants to dump wastewater into the Straight. These are not ecologically-focused decisions. When will the Nova Scotia government wake up and take a step forwards? I have no interest in supporting an industry that is destructive to the environment and to be honest, neither does anyone else in the forest industry that I have talked to. Northern Pulp held a meeting for its contractors, "asking them" to support their pipeline project. In fact, what they did was akin to fear-mongering. They threatened the contractors' livelihoods with the prospect of the mill closing. "Support us or you will lose your job." Please believe me when I say, this ultimatum has left us feeling helpless, guilty, and ashamed. I am personally not afraid to voluntarily abandon my post in forestry and I will not stand idly by if this effluent pipeline is approved.

I thank you sincerely for taking the time to read my letter and consider the points I have made. I am not an expert in environmental science but common sense and passion mixed with pride for our Straight compel me to take a stance, no matter how small of an impact it may have. I ask that you either a) reject Northern Pulp's proposal, or b) step aside because of conflict of interest and hand over the environmental assessment to the Canadian Environmental Assessment Agency.

Thank you,

The following is a list of friends and family who would like to show support for my letter, but who have not had the time to write their own due to the very short time period that was given to the public to respond

10 names have been redacted as per Section 20(1) of the FOIPOP Act.

To the Honorable Margaret Miller
Minister of Environment
Province of Nova Scotia
Halifax, NS

Via email to: 'ea@novascotia.ca'

Re: Project to Replace Boat Harbour Effluent Treatment Facility

Dear Minister Miller,

I will admit to having read Joan Baxter's book, "The Mill" however I think it is quite fair to say that trickery and overly-generous enticements were used by a previous Nova Scotia Government back in the 1960's to bring this mill to Abercrombie Point and that bullying and expensive Government handouts were used to keep it in operation over the past 50+ years.

I support the fact that we need jobs but not at such a heavy cost.

Based on past behaviours exhibited by the owners of this mill as well as previous Provincial governments I am concerned this project will continue to expose the Northumberland Strait fishery to the risk of industrial chemical pollution. It will also expose the 11 Kim's of the overland pipeline route to the ferry terminal to the same risk.

The environmental damage done to Boat Harbour in the past is a disgrace and an embarrassment that must not be repeated.

For most of the past forty years my family and I have spent a lot of time visiting our extended family in Pictou County. We camp at Caribou - Munroe's Provincial Park, swim at local beaches from Melmerby Beach all the way to Cape John.
We canoe and join family on boating trips from downtown Pictou to Pictou Island, stopping to fish mackerel and enjoy a dip in the Strait along the way.

The Northern Pulp mill was originally designed for a thirty year expected life according to Ms. Baxter's research. We are now at year 52, well past its "Best Before Date."

This means the mill will require significant investment from its owners if they are to adequately maintain it against wear & tear and mechanical break down as it ages further. But then again, why should they worry about upkeep if we have provided them with an Indemnity Agreement that transfers that burden onto the backs of Nova Scotia taxpayers?

We do not need nor can we afford another Sydney Tar Pond type of environmental disaster although Boat Harbour is clear proof that such a disaster already exists.

I reviewed the Dillon Report on this effluent pipe project and could see no mention of what the current useful life expectancy for this mill is.

I saw on page 42 of the online Report that, “the continued operation of the NPNS will ‘meet global market demands and supports the local and provincial forestry sector’...”

I would argue it is the other way around. I would say that our Nova Scotia forestry sector and the Nova Scotia tax payer are supporting the Northern Pulp mill. I flew over the eastern mainland in the fall of 2017 and was shocked to see the many square miles of grey wasteland between Abercrombie Point and the Eastern tip of Guysborough County. That will take a long time to replenish.

Then there is the health risk of the aerial spraying of glyphosate to kill off the deciduous trees in order to allow only coniferous trees to grow back for the benefit of this mill.

I believe the past negotiations and agreements between the Province of Nova Scotia and the various owners of the Northern Pulp mill were not made with the best interests of all of the people of Nova Scotia in mind and therefore should be considered to be null and void ab initio.

Sincerely,

x payer since 1975.

Project: replacement_effluent_treatment_facility_project Comments: After living in Pictou County for my whole life and loving places like Powels Point in Little Harbour and Melmerby Beach, Ive been horrified by what I saw at Boat Harbour.We know not to eat the clams or mussels at Powels Point, they make you sick. We used to have class trips to Boat Harbour. I got in trouble as kids we all knew that what was happening at Boat Harbour was wrong, I even got in trouble by my teacher for trying to talk about how I felt durning the tour. If you see Boat Harbour you will never approve effluent to be pumped into the Strait. Please, for the sakes of my children and for all who love this province we call home, please no pipe. Systems fail to often to jeopardize the water that surrounds us. There has to be another way. Name: Email: @hotmail.com Address: Municipality: : Privacy-Statement: agree

Subject: Please Reject NP's Replacement Effluent Treatment Facility Proposal
Date: March 9, 2019 7:40:28 PM

Dear Minister Miller;

I am writing to express my deep concern about Northern Pulp's proposal for a effluent pipe to pump waste water into Caribou Harbour and the Northumberland Strait.

I am a resident of Halifax but I grew up in the town of Pictou and I have a summer cottage in Caribou River. I am a social worker by profession and I hold a Master of Arts in International Development Studies and a Master of Social Work.

The pulp mill has had a devastating effect on the ecosystem of Pictou Harbour. As a young child I was able to swim in the Harbour but that changed after the mill was built due to contamination. Today, one can easily find deformed sea organisms along the beaches in the mouth of the Harbour and notice an ugly brown sludge on the water's edge or floating on top of the water in the middle of the Harbour.

With the upcoming and very much overdue closure of Boat Harbour, Northern Pulp has been unable to put forward a plan for effluent treatment and discharge that is convincing in terms of environmental protection. Caribou Harbour remains a diverse and rich ecosystem as does the surrounding waters of the Northumberland Strait. In summer we are able to swim, boat, fish, dig for clams and pick muscles in these waters and beaches. Our fishermen, their families and local businesses rely on this rich ecosystem for their livelihood and prosperity. The proposed effluent pipe threatens our entire way of life and must be stopped.

Traditional First Nations communities are said to plan their actions based on their effects seven generations into the future. I urge you to do respect this principle and reject Norther Pulp's proposal.

Sincerely,

Subject: MY EA Submission on the Replacement Effluent Treatment Facility Project by Northern Pulp
Date: March 9, 2019 7:51:09 PM

Good Day. This serves as my submission for the environmental assessment of the subject project, in Pictou County, Nova Scotia.

Ii was born and raised in Pictou County, Nova Scotia. I am very proud of that fact, and of my family, and friends who have also become family over the years, that either reside in Pictou County, or elsewhere in Nova Scotia. I have a great deal of respect for the hardworking people of Pictou County, who have had to withstand the water and air pollution caused by the paper mill, now for well over 50 years. That fact makes it very difficult for me when I think of its ongoing effect on the health and well-being of all those who live both in that area, and nearby, and also its effect on the whole community, both environmentally and economically.

Others are qualified to speak as to the scientific evidence of its environmental harm to the ecosystems, to its negative impact on our resource, business, and tourist industries that rely on environmental well-being, and to its impact on the medical health of our people, adults and children alike, over the years.

I can speak only from my own experience, as a person who after decades of working elsewhere, decided upon retirement, to come back to Pictou County to buy a cottage, and spend several months of each year there, with my family members and life-long friends. It is also special time to have our grandchildren come to spend time with us at the beach, for them to explore animal life along the water's edge, and find new playmates there as well. The creation of all these memories together, with family and friends, very close to the actual land where I was raised, is what matters most, at this time of my life.

But then there is the pulp mill, which continues to create the air and water pollution caused by its processes, and its impact on human health, on adults and children alike, of which our well-respected doctors have ongoing professional experience.
Healthy employment levels in a variety of sectors in Pictou County are absolutely required of course; but one's health comes first, before one can be employed or continue to be employed, and actually get to enjoy the results of that labour.

I have great faith in the resilience and capability of the people of Pictou County. I believe that the local community as a whole will be very capable of responding positively to future opportunities for economic growth and prosperity, once the crucial environmental issues have been both fully acknowledged, and fully addressed, by those in positions of responsibility in this matter. This absolutely needs to be done, in the best interests of all who live and work, or visit our historic, and very treasured part of Nova Scotia.

Sincerely yours,

Sent from Mail for Windows 10

Subject: Response to Norther Pulp"s Environmental Assessment
Date: March 9, 2019 8:07:17 PM
Attachments: submission to NSE re Northern Pulp.docx

Please find attached our concerns regarding Northern Pulp's environmental assessment in relation to their new replacement effluent treatment facility.

Thanking you in advance for reading my letter of concern.

Thanks

Dear Margaret Miller and Nova Scotia Environment team

We are writing in relation to Northern Pulp's Replacement Effluent Treatment Facility Project. We own two businesses in the Province of Nova Scotia. A commercial fishing business located out of Caribou, NS and a small trucking company located out of the Town of Pictou. We are parents and property owners and most importantly tax payers of Nova Scotia.

After weeks of reading the environmental assessment submitted by Norther Pulp, I have many concerns; however, I do know there are hundreds of people including chemists, biologist, doctors, engineers, scientists and other knowledgeable folks that are writing in with their concerns regarding same. On that note, the following document submitted by us will include a bit of our personal issues and of course leaving out lots to the professionals that have already submitted.

The EA starts off with the Executive Summary providing a table indicating the "significance of project-related residual environmental effects on 18 items. And for some miraculous reason every single one of them is assessed at "NS" or No Significant Residual Environmental Effect Predicted". Well I can predict that I will win the lottery next year but the chances of that are slim to none. So, lets cut the bullshit!!! So as Joan Baxter states in her article in the Halifax Examiner on March 5th, 2019 *Northern Pulp's environmental documents: In other words, the on-site Activated Sludge Treatment system will effectively treat millions of litres of toxic pulp effluent a day, every day, without a hitch. The 36-inch diameter pipeline that will run 11.4 km across the causeway and then overland beside Highway 106 to Caribou Harbour will never leak or spill its contents in the Pictou watershed, or negatively affect the scenic landing point for the PEI ferry that brings tens of thousands of visitors to Nova Scotia each year. The 4.1-kilometert pipe into the Northumberland Strait that will dump millions of litres of effluent a day into the rich fishing grounds will not harm fish habitat or the ecosystem. The "dewatering process" of the sludge from the treatment facility will work well, and there is no need to worry about burning it in the mill's power boiler, even though that boiler has already caused many emissions problems.*

Within this document we will give our reasons why this project will cause adverse effects or significant environmental and health effects, negative economic effects and mitigation or lack there of, of same.

Some of our concerns with Northern Pulp's environmental assessment:

In this section we will refer to some of the concerns, discrepancies and wrong information that has been submitted by Northern Pulp.

Human Health

I live approximately 3 km from the stacks at Northern Pulp. We suffer with our breathing here. Especially on humid days. The smog sits on top of our Town and penetrates into our homes and our lungs. We cannot open our windows. I had to cut 22 trees out of my yard so that the heavy smog would have a chance to flow through as opposed to sit stagnant. I know that none of you reading this right now know exactly what that means. Maybe in the next 20 days you should take a drive down to Pictou or Pictou Landing and take a nice long inhale. You should come in the middle of the night to see 23 stacks blowing smoke while people are sleeping and then only 11 in the day. This is a regular occurrence as I work night shifts and have the pleasure of witnessing this questionable activity.

Section-9-15 Human Health Evaluation: the consultants compared the "potential human exposures and risks associated with a marine treated effluent discharge" from a Kraft pulp mill in Bell Bay Tasmania. However, it would be impossible to compare the two because **IT DOES NOT EXIST!!!! Remember this is the section where they assessed the possible impacts of human health! And remember that they determined that by comparing the two that there would be no significant health impacts!! From a mill that DOES NOT EXIST!!!!**

This is all I should have to write, but I will continue……

Mercury:

Oh wait! Northern Pulp didn't mention all the mercury that they have buried on their property! In fact, they didn't mention any of the mercury. Nova Scotia Department of Environment know about the Mercury, Northern Pulp knows about the mercury and Dillon Consultants know about the mercury; yet no mention of it in the environmental assessment!

Mercury is an environmental toxin which is persistent and bio-accumulates. It does not "go away" it can build up in the environment and in the food chain. There is no known safe level of human exposure to mercury.

Northern Pulp consultants told me at the open house that there is no mercury in their effluent. When I read the reports from the raw effluent spill from 2014 there were substantial amounts of mercury found. So why did they lie to me? Maybe they didn't think people would get their hands on those reports?

It is my opinion that given the fact that Northern Pulp has neglected to include this extremely crucial portion of concern, that the Minister of Environment should request a full impact study on this material alone. And demand proof that there is no mercury on site at Abercrombie Point as Northern Pulp is claiming

Section 8.3 Soils and Geology in relation to scallop fishing

The assessment talks about the type of bedrock along the land portion of the pipe but fails to mention any of the bedrock along the marine portion. What we do know about the bedrock along the marine portion and the outflow portion is that it is constantly changing. fishes scallops along some of this area. From year to year as he drags the ocean floor and the materials come up in his baskets onto the boat, he gets a first hand look at what is on the ocean floor. From his 23 years of experience not one year is the same as the next in the exact same location. For example (North South 14,316 and East West 29,820) in 2017 had huge boulders and huge rocks (granite, coal, shale, sandstone are some examples). So big in fact, that the weight broke cable. But in that exact same location in 2016 the ocean floor had mud and only mud. This is the same with all areas that fishes every year for the last 23 years.

There is no mention of coal. There is a substantial amount of coal on the ocean floor sub surface as well as surface all along the pipe location and outflow location. A conversation I had with a geologist from Nova Scotia said "disturbing coal deposits releases methane. Methane in either air or water isn't good. The submission is missing this information! Information that is a necessity to evaluate the impacts of the project.

I believe more information on coal deposits and the effects of disturbance and the geological report for the marine portion of the project is needed before the Minister can make a decision.

Table 8.6-2

Seasonal Sensitivity of "freshwater" fish species potentially occurring in Local Assessment Area

The chart shows zero sightings for all species including white sucker, mummichog, minnows, perch, rainbow trout, gasper au, Atlantic salmon, brook trout, and brown bullhead. sees minnows, mummichogs, rainbow trout when he is smelt fishing. They are known to inhibit brackish waters and fishes smelts adjacent to where this sight test was conducted. Gaspereau frequently come up in his traps and are a feeding fish for lobster. It is very well known that Atlantic Salmon are certainly plentiful in the area.

Just because someone put a net out for a day and didn't catch any of the species on the list, does not mean they don't inhibit the area!!

Fishing and Recreational use of the Outflow Area:

THERE IS 100% COMMERCIAL FISHING AND RECREATION ON, NEAR, AROUND THE LOCATION EXTENDING THROUGH THE WHOLE GULF REGION!

We hold licenses for 7 species in the exact location and beyond the pipe and outflow location. They include smelts, herring, swordfish, scallops, mackerel, squid and lobster. We recreationally fish bar clams, bass and mussels from the exact locations as well. Our freezer is full of bass, clams, lobster, scallops. If this pipe goes out and pumps and unidentified liquid at a relentless amount of 85 million liters per day, every day, all of this will be ruined. I cannot consume, nor give my child and other family member, friends and stranger, food that has ingested or absorbed an unidentified effluent!!!! Think about it. Or better yet, I will go over to the lagoon at Boat Harbour and grab a big pot full of effluent and cook you all up a big feed of lobsters, then you can make a decision on if this should go out into the Strait!

Recreation on this body of water and the surrounding beaches is huge! Boaters, swimmers, kayakers, beach combers, cottagers and a Provincial Park.

PERSONAL ECOMONICS

was 22 years old when he bought his commercial fishing gear and licenses. He is a third-generation fisher and fishing is in his blood. This isn't a cliché statement, this is the reality in a fishing community in NS. We have invested 1.6 million dollars over the years into this business and this is our retirement. If this project is approved and a pipe goes out into the Northumberland Strait, we will lose our stewardship. We are done! Everything we have worked for will be gone. Please consider our plea. We hire local people, we invest in the local economy. We pay substantial amount of taxes each and every year.

End Summary

I am keeping my submission short because I know of all the professionals that are taking on each and every piece of this assessment will have a thorough and fact-based submission so I will leave the scientific and technical stuff to the professionals.

We feel that Northern Pulp's submission does not prove a lack of significant risk, and is missing critical data on many issues. There is insufficient evidence to know exactly how broad any damage might be. The company's claim that damage will be "minimal" is not credible because they have no data to back up claim….just words. Fisheries, tourism and outdoor recreation are very important economic factors that should absolutely not be put at risk. As far as consultation goes: The United Nations Declaration on the Rights of Indigenous Peoples requires not just consultation, but consent by the local Indigenous population. Pictou Landing First Nation is opposed to this proposal. The company promised community consultation and we did not receive that after the first proposal was squashed by the company. The must reject Northern Pulp's proposal and close the effluent treatment, Boat Harbour on schedule.

Please reject this proposal by Northern Pulp! We cannot mitigate the Northumberland Strait. We cannot ruin an entire fishing industry. We cannot ruin our environment. We cannot put people's health at risk!!

Project: replacement_effluent_treatment_facility_project Comments: This is a positive project, proven technology that will treat effluent to a very high standard of safety for fish and humans. Similar process at Port Hawkesbury has run successfully for close to 25 years. Unfortunately much of the media reporting about this project has been extremely biased and not fact based - this is not about jobs versus environment - it is about protecting the environment and the jobs in the forest industry! I support this project completely. Name: Email: @gmail.com Address:

Subject:	Proposed Project Comments
Date:	March 9, 2019 8:37:53 PM

Project: - Choose - Comments: I wish to convey this project, as presented, should not proceed. The life expectancy of the mill was reached back in the late 1980s, and it would be sad if it is allowed to continue to operate, poisoning our water and air and making people and ecosystems sick. Little analysis has been done on the impact on larval lobster and the Northumberland Strait is already loaded with many cumulative environmental stressors. Adding pulp waste directly to the Strait is a completely different process than running it through the Boat Harbour Tidal Lagoon with a 30 day retention time that allows solids to settle. Adding the hot pulp mill effluent with the slurry of toxins directly into the Strait has the potential to really impair the Northumberland Strait well beyond what it is now. It could be very damaging to commercial fisheries, which I am sure nobody wants to destroy. Given the risks and scale of this project, I dont see how anyone could logically say it the impacts can be mitigated. On the Forestry side, the crown forests of Nova Scotia have been largely destroyed, given away to wealthy foreign companies over the last 5 decades to produce low value pulp. There isnt much left to cut, and so why keep a dying industry with depleted resources going? We should be building our forests to be climate resilient and harvesting wood only through selective cutting for the highest value, not clear-cutting land for low-value pulp. The time has come for change, and the days of industry polluting and destroying public resources, at taxpayers expense should be over. I say yes to human health, clean water, biodiversity and sustainable resource-based industries and NO PIPE, NO MILL. The Mill has had ample opportunity to put a better plan in place, and the fact they did not do their homework simply shows their commitment to NS. I feel the NS government is in a serious conflict of interest since they are financing a lot of the work while their job also entails regulating the mill. I feel the proposal would pass the Federal Environmental Assessment process, if one were required. This really disturbs me, but our standards need to change with the times. Dilution should not always be the cure for pollution. We know better now, or at least we should. At the end of the day, if this project proceeds, the legacy of environmental damage will continue. Thank god we have a fabulous book that provides a social lens perspective on the mill since its early development back in the late 60s. We now have the opportunity to learn from the past mistakes and put a priority on human and ecosystem health. We need to do better than this proposal to simply dump it directly into the Strait. My submission in PDF format included

– Fisher
Chairman; Gulf NS Herring Federation

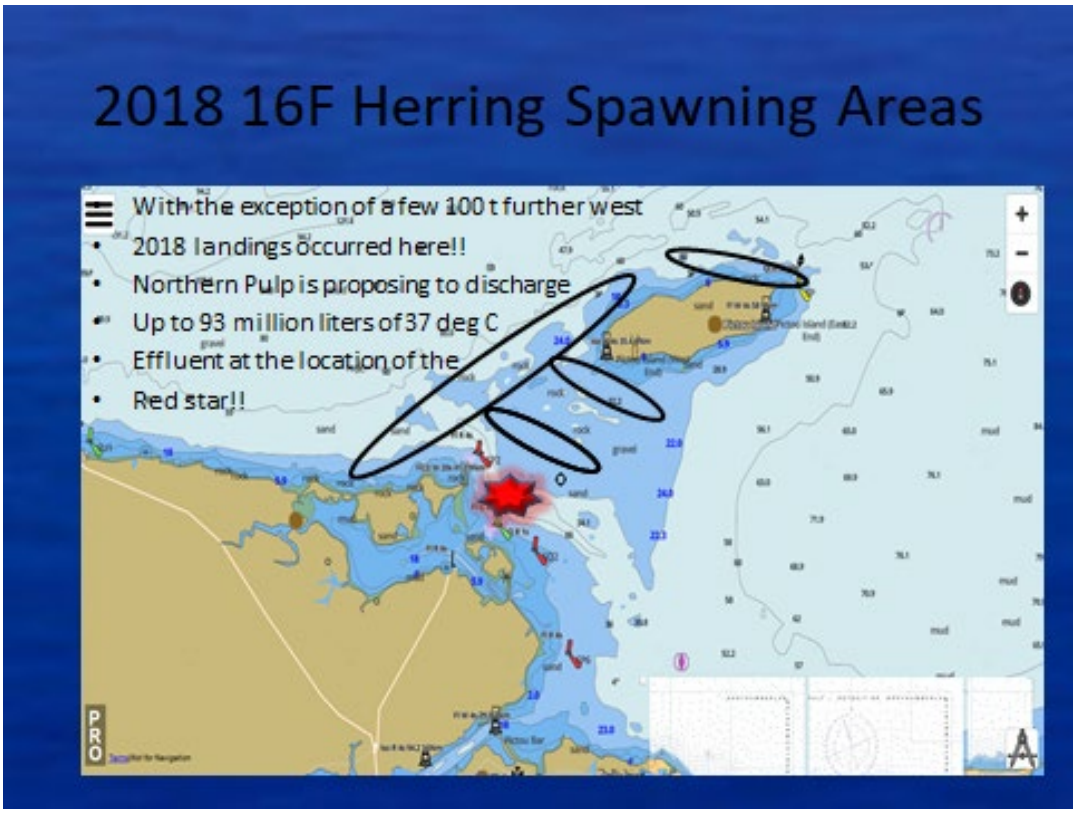
Feb 23, 2019

To: Nova Scotia Dept. of Environment

Dear Sirs/Madams,

Northern Pulp, a bleached Kraft pulp company (and the Province of Nova Scotia) are planning to construct an effluent pipe with a difuser at the location of the red star in the diagram below. The pipe is to replace the Boat Harbour Effluent treatment facility due for closure in January 2020. Boat Harbour is deemed to be one of the most toxic sites in Canada and has been a horrific injustice inflicted on Pictou Landing First Nations for over half a century.

This proposed pipe is designed to discharge up to (66)(93) million liters of 37 degree + 'treated' effluent daily into the Northumberland Strait, right in the middle of the last major active spawning area for 16F herring. The complex tides in this area, both in speed and direction, would ensure that the effluent would settle out across the entire remaining herring spawning grounds. This is the most dynamic area in the Eastern Northumberland Strait and a critical spawning ground for Lobster, Rock Crab, Herring, Ground fish and many other species.



The effluent will pour into Caribou Harbour on the rising tide and settle atop oyster beds and the salt water intake of the only fish processing plant in the area. On any given day during lobster season 100,000 pounds of live lobster could be floating in cars within Caribou Harbour directly in the path of the effluent stream.

The local Herring Spawning Stock is depleted and in the Cautious Zone and the reason for the decline is not understood. This is a Gulf of Saint Lawrence wide phenomenon. The local spawning area

has compressed in the past few years, as the stock declined to the areas outlined above. Other areas in the Eastern Gulf are in even worse condition. The Fisherman's Bank population has all but collapsed and the Northeast (North Lake) component was absent this year!

The Gulf of St Lawrence is an inland sea with counter clockwise currents that only exchanges its waters with the Atlantic once a year. It is one of the most precious marine ecosystems on earth with thousands of marine species who, spawn, nurse and migrate annually and has sensitive life stages of marine organisms present year around. It provides sustainable multi species fisheries for coastal communities in NS, NB, PEI, QC and NL. Given the rapid deoxygenation now happening in this fragile body of water (see link below), the Gulf of St Lawrence needs immediate protection, not further degradation. Most seriously, it does not need 'treated' Kraft bleached pulp effluent going into sensitive herring spawning waters, now or ever.

http://www.digitaljournal.com/tech-and-science/science/new-study-gulf-of-st-lawrence-shows-a-dramatic-oxygen-decline/article/532340

Given that DFO scientists recently reported a disturbing picture for the southern gulf of St Lawrence cod, warning of extinction by mid century, (see link below), where is the Precautionary Approach? Habitat Management? Marine Protected Regions?

https://www.cbc.ca/news/canada/nova-scotia/southern-gulf-of-st-lawrence-cod-could-be-extinct-by-mid-century-report-1.4966889

The Proponents paint a picture of this effluent as almost pure holy water. They claim it surpasses all Provincial or Federal guidelines for effluent discharges yet it created one of the most toxic sites in Canada at Boat Harbour. Any online search of pulp mill effluent turns up articles with quotes like,

- *Environmental effects on the marine environment are particularly poorly researched, even though some of the limited amount of data available suggests that lignin breakdown products of high molecular weight are not only persistent, but also highly toxic to sea urchin eggs, sperm and mussel larvae. (Gary Cherr, Bodega Bay; paper is available from ECOPOL)*
- *The role of non-bleaching factors is big and pulp wash water for example, can be more toxic than bleach plant effluent.*
- *chlorate will compete with nitrate for uptake by algae, yet chlorate acts as a herbicide rather than a nutrient.*
- *Chlorate is efficiently removed through anaerobic secondary treatment systems (eg. Lagoons), but removal in activated sludge systems is not as successful.*
- ***These long-term fish exposures are laborious, time-consuming, and expensive. However, they provide some of the most convincing evidence linking PME (pulp mill effluent) exposure to reproductive effects in fish.***

The list goes on and on with reproductive effects being flagged in most instances. Poorly understood "reproductive effects" are not too comforting when the herring stock is in need of rebuilding and this project proposes to saturate the spawning grounds with toxic effluent.

The proponents claim this effluent will be non-detectable at 100 meters. That's magic. I would question the sensitivity of the detectors or what exactly they are attempting to detect. We challenge you to go down to Boat Harbour and stand there for 10 minutes. The treated effluent is certainly detectable there at 100 meters.

This Effluent Pipe and proposal has been presented twice in the past, first in 1994 and a variation in 2004. The first of these, “The Initial Environmental Assessment for the Boat Harbour pipeline and diffuser” proposal was presented in September of 1994 and “Returning Boat Harbour to a Tidal Estuary” in 2004. Neither passed muster at the time and either failed environmental assessment or were abandoned for other reasons. Details in writing on the abandonment of the proposals are sketchy but no PIPE ever went out into the Strait.

Your Nova Scotia Department of Environment has diminished this toxic pipe proposal to “an addition to an existing facility” and as such, subject to only a Class 1 Environmental Assessment rather than a more rigorous Class 2 assessment. This is inaccurate and irresponsible. The increase in suspended solids with this proposed new AST system and its inevitable settling on spawning and nursery grounds should trigger the most vigorous assessment and likely scuttle the project entirely. We implore you to examine this project closely and recommend it for a more vigorous and comprehensive Class 2 assessment.

Respectfully,

- Fisher

Subject: Letter in response to Proposed Effluent Treatment Facility Northern Pulp
Date: March 9, 2019 9:29:38 PM
Attachments: Submission.pdf

March 1, 2019

Dear Minister Miller,

I am writing in response to the Northern Pulp Replacement Effluent Treatment Facility Project. I am a resident of the town of Pictou, an outdoor adventurer, a social worker working locally with children and families in the community, and a member of a fisher family. My partner and his father have harvested lobster and herring from the Northumberland Strait for 25 years.

In many respects, my position on this topic is largely intersected by the tensions in my identity as a resident of Pictou County, a civil servant to the community, and member of professional body devoted to advocating and promoting social justice and equality for all persons.

In my submission, I will express three (of many) concerns as they relate to the proposed project, and the process in which this submission has been reviewed with the community. These three concerns include the lack of community consultation, the potential impact on the Pictou Water Supply, and the lack of concrete evidence based assessments included in the environmental assessment at time of submission.

As a member of this community and a taxpayer in the province of Nova Scotia and the town of Pictou, I have become very concerned about the proposed project to replace the current Boat Harbour Treatment Facility. As a member of the Nova Scotia Association of Social Workers it is inherent in my professional values and ethics to uphold equality, autonomy, and social justice for all. The treatment of the first nations community in Pictou Landing over the past 50 years is abhorrent, and I acknowledge that Boat Harbour must close.

As a member of my community, I have worked to educate myself on the issues surrounding the Northern Pulp Effluent Treatment Facility Project over the past fifteen months since the announcement of the initial proposed project. My involvement with the Friends of Northumberland Strait group has included participating in planning and coordinating efforts as a committee of well-organized volunteers. Despite having substantial background knowledge on the subject and being a university educated professional, reading the entire proposal, consolidating my concerns, and articulating my questions has been extremely challenging. I have read much of the documentation provided by Northern Pulp, attended the open houses in December 2017, submitted questions and concerns, and I still find that the method in which this information has been communicated to the wider community has not been accessible to the people that a decision of this magnitude will impact. With a below average literacy level in the province of Nova Scotia (Literacy Counts, Statistics Canada, 2010) which is compounded by other socioeconomic issues faced in rural communities such as Pictou County, the process to review, evaluate, and respond to the 1700-page proposed project has not been fair.

The new route (which runs through the watershed that my community draws its water supply from) has not been presented to my community (the Town of Pictou) in the form of an open house. The public has had limited time and opportunity to digest the volume of materials that have been provided to them to consider in this very important proposal, and they have not been provided an opportunity in the form of a public consultation to review and reflect as a community on the project. In the absence of open houses (with the new proposed outfall location in Caribou), town hall meetings, and accessible, factual, and comprehensive information, the public and community at large is at a tremendous disadvantage to communicate and understand their concerns as they relate

to the proposed project. From my work in the past with community development, critical aspects to build relationships and trust within a community come from open and transparent dialogue that includes all stakeholders. If this community, government, and corporation (Northern Pulp) have learned anything from the legacy of Boat Harbour, is that the community must be consulted in a transparent, truthful, accessible, and meaningful way.

In Section 6.5.1 under Engagement Activities of the Project Re-Design (Northern Pulp Replacement Effluent Treatment Facility, Environmental Assessment Scopes and Methods, 2019, pg 106) there is an absence of engagement with the broader public, including an absence of engagement with the Residents of the Town of Pictou. As the project will have a footprint over portions of the town's water table (Environmental Effects Assessment, Northern Pulp, pg 186), it is my understanding the people of the town of Pictou and the Municipality of Pictou County would be considered stakeholders, and the insinuation that Northern Pulp has met with all relevant "stakeholders" throughout the course of the consultation period of this project is misleading.

As a resident of the town of Pictou, the water supply issue is of tremendous concern. The possibility of a spill or leak in the pipe over the town's water supply, and what impact this could have has not been addressed in the Environmental Assessment Registered by Northern Pulp. In October 2018 the town of Pictou announced the opening of a 5.8 million dollar investment to improve water quality and build a Water Treatment Facility (www.townofpictou.ca, New Water Treatment Plan Officially Opened, 22 October 2018). Water quality issues have been longstanding and painstaking in the town of Pictou. I have relatives who live in Pictou Landing First Nation who in 2014, 2017, and again in 2018 have been unable to drink their tap water due to spills, and possibility of contamination from the effluent being transported and treated in Boat Harbour. In Section 8.5 outlining Groundwater issues and their relation to the Town of Pictou water supply, there is an absence of clear, documented mitigation efforts that are evidence based to prevent contamination. There is an absence of reference to a specific mitigation/ground water monitoring systems that would alert necessary parties to a spill or leak, and possible contamination of water supply. The environmental assessment references that it is still unknown and unclear what exactly will be in the effluent, the parameters of monitoring and understanding the implications of a spill into a water table are yet to be determined.

The Environmental Assessment is missing important facts. On Page 12, paragraph 3, the Environmental Assessment reads "due to the EA registration timing, the study period did not facilitate a full biological field assessment for the corridor". Unfortunately, upon review of the document, there are several assessments missing from the report, and frequent reference to "will be completed upon permit" and "will be completed upon approval". Reasons listed include "seasonal constraints", "physical opposition and obstruction" (pg 12). These studies include things that are seemingly critically important to a decision on an approval for the project, including marine life studies, human health studies, and biological field assessments. This illustrates a lack of information and an incomplete assessment of the true impacts of the proposed project.

As a child I had friends who attended the Camp Maclellan United Church Camp when it was open. MacLellan Memorial Camp is situated approximately 7 km from the Boat Harbour Treatment Facility. The camp has since closed, but what I vividly remember from hearing about my friends' time there, was that they were not allowed to swim in the ocean because of contamination. This continued, until the last year the camp was open (2015). In fact, the camp had an inground swimming pool due to the issues with water quality and contamination in the beach. In 2013 When I picked my little sister up from attending her week at camp, she had a wonderful time talking about memories with her friends, but acknowledged that it was a shame they could not swim in the ocean there, because of "the stinky Boat Harbour". The outfall location of the proposed project is approximately 4.1km from the Northumberland ferry wharf, taking it approximately 5km outside of one of the most popular beaches visited by tourists and locals around. The Caribou Provincial Park is where I spend every day walking, in the summer it is where I swim, and it is where I want my children to swim. Reflecting on what the water looked like in MacLellan Memorial Camp on the beach, and the contamination that occurred on that shoreline as a result of discharge into the strait following effluent treatment from Boat Harbour, I cannot help but think of the careful measures that were taken to prevent children from swimming in that water due to contamination. I am struggling

to understand how constant flow, with an undeterminable end, of effluent can be discharged within 5 km of one of our provincial treasures, Caribou Provincial Park, and jeopardize the ability of children and families to enjoy what this coastline can offer.

Based on what I have outlined above, there is not enough information available to approve the Proposed Effluent Treatment Facility Project as submitted by Northern Pulp. I am asking that the Minister order an Environmental Assessment Report, to allow the most in-depth and comprehensive understanding of the complex issues that could face this project, including the impact of adverse effects.

Thank you for your careful consideration and review of the concerns relating to this project,

Re: Northern Pulp Nova Scotia Corporation's Replacement Effluent Treatment Facility Project

This letter is submitted on behalf of the Ecology Action Centre (EAC), an environmental charity working since 1971 at the local, provincial, national and international level to build a healthier and more sustainable world. Our vision is 'a society in Nova Scotia that respects and protects nature and provides environmentally and economically sustainable solutions for its citizens'. The EAC works to catalyze change through policy advocacy, community development and awareness building. And, when required, we serve as a watchdog for our environment.

In that capacity, we respectfully request that the Minister reject Northern Pulp Nova Scotia Corporation (NPNS)'s proposal as outlined in their registration document under Section 34(1)(f) of the Environment Act "because of the likelihood that it will cause adverse effects or environmental effects that cannot be mitigated". We also cite that there are a number of areas in the registration document where crucial information is lacking or unknown, triggering Section 34(1)(a-c) requiring additional information and focus reports. We also cite Section 2(b)(ii) "the precautionary principle will be used in decision-making so that where there are threats of serious or irreversible damage, the lack of full scientific certainty shall not be used as a reason for postponing measures to prevent environmental degradation."

Despite its impressive volume, NPNS's registration document is very poor and fails to provide necessary information about key elements of their plan, including and importantly - the content of the substances they wish to pump in large volumes into the Northumberland Strait and the potential impacts that it undoubtedly will have on marine life and air quality. The registration document seems designed to obfuscate essential details, downplay them or intentionally omit them altogether. It essentially says there will be no impact of any kind. This is simply not credible. In Table E.1.1-1: Summary of the Significance of Project-Related Residual Environmental Effects Predicted. Every row and column of the table contains 'NS' which represents 'No Significant Residual Environmental Effects Predicted', including water quality, fish and fish habitat, surface and groundwater and the entire 'Accidents, Malfunctions and Unplanned Events' column. It is inconceivable that after NPNS's lengthy history of leaks, ruptures, over-limit emissions and other unplanned events that these predictions could be put forward credibly in a registration document for environmental assessment of this proposed effluent treatment facility.

NPNS has not done its due diligence to fully determine the potential impacts of their proposed project. It is the duty of Nova Scotia Environment to apply a rigorous standard of environmental protection when assessing risk and we do not feel that NPNS has provided sufficient information within their registration document to enable the province to complete the assessment. In light of this, the only acceptable decision is to reject the proponent's proposal for this effluent treatment facility. The potential for damage to our land, water and air from this proposed effluent treatment system is far too great for the province to grant approval.

The EAC's concerns about this proposed effluent treatment facility are numerous. Despite the very limited time available under this 'Class 1 undertaking' environmental assessment process (30 days) to review the proponent's registration document (1,586 pages spread over 17 documents), this letter outlines our primary concerns, which are:

- Use of an insufficient standard for effluent;
- The potential impact on the marine environment from the massive volume of effluent with its undetermined chemical and physical composition;
- Cumulative impacts and the fragility of the ecosystem of the Northumberland Strait;
- The risks associated with the effluent pipe and its pathway;
- Air pollution from burning waste sludge;
- Socio-economic impacts on fisheries and other sectors; and
- Indigenous opposition
- Lack of serious consideration of alternatives

Insufficient Standard for Effluent

NPNS had a responsibility to develop a solution that enables their operations to continue in Nova Scotia while preventing harm to the environment and the wider community. Rather than identifying an innovative solution which does these things, it is clear that NPNS's objective is simply to meet the minimum Pulp and Paper Effluent Regulations (PPER). The federal regulations are very old and are currently undergoing a major overhaul. NPNS will be required to comply with the updated PPER once the new standards are complete and accordingly, it is irresponsible for their effluent goals to just meet the existing standard. And this statement assumes that their effluent would meet the current standard, something that NPNS cannot guarantee since they cannot say what will be in their effluent until the new system is operational.

A key reasoning behind the proposed modifications to current PPER has been the ongoing degradation of fish habitat by most mills, even when in regulatory compliance. The PPER are primarily designed to prevent effluents that cause acute lethality to fish from entering nearby waterways (pg. 357) and do not deal with long-term cumulative effects or ecosystem impacts. Furthermore, according to Caroline Blais, the Director of the Forest Product and *Fisheries Act* Division at Environment and Climate Change Canada (ECCC), 70% of pulp and paper mills abiding by today's PPER have still shown deleterious impact on fish or fish habitat. A 2016 EcoMetrix study also found enlarged gonads and livers in fish tested near the current Boat Harbour effluent treatment facility's outfall location, despite the fact that Northern Pulp has routinely passed the acute lethality testing. Director Blais, in presentation for the Prince Edward Island Standing Committee on Agriculture and Fisheries in February 2019, described widening the scope of deleterious substances that may call for regulation and "reviewing the regulatory limits for existing and new substances," as central to the government's PPER modification effort. This process will also seek to develop new regulations to treat nutrient inputs, which to date have not been addressed in PPER legislation. NPNS's proposal has not adequately addressed how the company intends to meet new and more stringent effluent regulations that the federal government is working towards.

Simply meeting the PPER is a tremendously low bar to set in environmental protection and is no guarantee that harm to the environment and ecosystem will not occur, only that outdated regulatory maximums of permissible harm might be reached. This is unacceptable, particularly since NPNS cannot even identify what will be in the effluent - a major red flag that this undertaking carries unacceptable levels of risk of impact to the environment and the legitimate interests of other stakeholders. Nova Scotia Environment clearly stated to NPNS that their EA must go beyond the parameters in the Federal PPER. Their proposal as outlined in the

registration document does not do that. Aiming to achieve the lowest possible standard after decades of causing significant environmental damage to the natural world and communities surrounding the mill is simply not enough.

Effluent Content and Potential Impacts on the Marine Environment

The volume and toxicity of the liquid waste produced at the NPNS mill is significant. Boat Harbour provides incontrovertible evidence of the impact of the effluent to the current "receiving waters" - the area is devoid of life. Redirecting the effluent into the Northumberland Strait and the lower Gulf of St. Lawrence will certainly be detrimental to the health and productivity of the new "receiving waters". But unlike Boat Harbour, where most of the damage to date has been contained (and will cost taxpayers hundreds of millions to clean up), the potential damage to the Northumberland Strait will not be easily contained and will be impossible to clean up.

The Northumberland Strait is a relatively shallow area with slow moving currents far from the open sea. This makes it a very low "flushing" system. It takes approximately a year for the water to fully exchange. Northern Pulp's own reports say that on top of 60 to 80 million liters of liquid effluent they also anticipate releasing up to four tons of suspended solids in their waste water each day. In addition to that it is important to note that every drain, toilet and sink inside the mill is attached to the effluent disposal system meaning that in addition to human waste every oil or chemical spill inside the plant ends up in their effluent system. Test results in the current receiving waters (Boat Harbour) show the presence of dioxins, furans, chlorinated compounds, halogenated organic compounds and traces of heavy metals. These substances are known to have serious negative impacts to aquatic and other life. In addition to the chemicals and solids produced in the pulping process the new effluent treatment system "will require several chemical inputs, including urea, phosphorus, sodium hydroxide, sulfuric acid and an anti-foam agent to support its process." (pg. 46). So these too would be sent out into the Northumberland Strait. With so many deleterious inputs it's no wonder NPNS doesn't know what will be in their own effluent stream.

Dioxins and Furans

Research from other pulp and paper mills can provide insight on the potential risks to the marine environment associated with some of the products referenced in NPNS's project proposal. In British Columbia's Howe Sound, the Port Mellon and Woodfibre bleach kraft pulp mills contaminated the local waters so badly that several fisheries had to be shut down in the 1980s. This was due in large part to the dioxins and furans released as a byproduct of the chlorine bleaching process, the same process used by NPNS. Dioxins and furans are toxic, carcinogenic and bioaccumulative pollutants, posing a significant threat to marine species and human health via ingested seafood or otherwise. These compounds have been linked to cancer and diabetes, among other serious conditions.

In 1992, national Pulp and Paper Effluent Regulations (PPER) were put in place to mitigate harmful impacts to fish habitat, and the marine life at Howe Sound slowly began to recover. But while the dioxin and furan content in the Sound's commercial fish and crab species have been reduced by 95% or more since that time, in three of eight Dungeness crab samples collected near the Port Mellon mill in 2012, the dioxin and furan content still exceeded Health Canada's safe-consumption criteria. Federal advisories to limit crab consumption remain in effect in the area to this day. The same results also held for testing done on Dungeness crab near the Woodfibre mill, despite the fact that Woodfibre was in a relatively good "flushing" position at the mouth of the Squamish River, up until the facility's closure in 2006.

NPNS's registration document, in Section 1-7, states that "Dioxins and furans in [Northern Pulp's] effluent have virtually been eliminated since the conversion to chlorine dioxide bleaching in 1998. NPNS has never exceeded the limits as per the Pulp and Paper Mill Effluent Chlorinated Dioxins and Furans Regulations." But we know that during NPNS's 2014 spill, on sacred burial grounds at the Pictou First Nation (PFN), proved that

at least five distinct dioxin or furan compounds were indeed still present in the mill's effluent, sixteen years after that conversion to chlorine dioxide bleaching. One of the dioxins was detected more than a kilometre down the beach from the spill site. ECCC regulations stipulate that dioxin and furan content must be non-detectable in pulp mill effluent. In addition, NPNS was found exceeding the daily release allowance for suspended solids by almost double the legal limit. Ultimately, the mill was fined $225,000 for the incident. Today, NPNS refuses to release the full suite of information on the components of the effluent they would see released into Northumberland Strait under their new proposal, and claims that the risk of contamination to marine habitat is "Not Significant". This is simply not credible.

In an attempt to explain this lack of transparency, the NPNS registration document states, "At this time, effluent chemistry characteristics (including the specific substances present in treated effluent and their anticipated concentrations) will not be known with certainty **until the project is operational**" (pg. 489). An expectation that NS Environment would grant approval to this project without provision of full details of the content of this effluent to be discharged into the Northumberland Strait should be extremely suspect, particularly given the company's track record of non-compliance. This includes not only the regulatory disregard displayed during the 2014 PFN spill, but also another spill by the Mackenzie Pulp Mill Corporation, owned by Paper Excellence (NPNS's parent company). In this case, Mackenzie Pulp was fined $900,000 and added to the Canadian Environmental Offenders Registry for violating the *Fisheries Act* by neglecting to properly treat the effluent spilled into British Columbia's Williston Lake on two occasions in 2014 and 2016. Paper Excellence has proven in spill scenarios in both Nova Scotia and British Columbia that their standard of care is simply not high enough for Maritime citizens to entrust this company to operate within the bounds of legality, let alone safety, in the Northumberland Strait.

Additionally, it is important to consider the cumulative effects of adding the toxins from NPNS's effluent into the proposed discharge area. In 2002, a study conducted on Nova Scotia's North Shore tested mussels for leukemia. At a site just 500 metres from the current Boat Harbour Treatment Facility outfall location, 30% of the tested mussels were infected. At a distance of one kilometre, 23% of the tested mussels showed signs of leukemia. In contrast, 56% of tested mussels in Pictou Harbour showed leukemia - a higher rate because of the dumping of untreated sewage at the time. Conversely, mussels tested in Merigomish Harbour did not show any effects of leukemia. In the end, the scientific team pinned the results on both municipal and industrial waste products. With the proposed level of effluent expected to be released into the Strait under NPNS's new plan, we may risk a future in which continued inputs render the local area entirely unusable for shellfish aquaculture or shellfish harvest altogether.

Total Suspended Solids (TSS) and Cellulose Fibers

NPNS public relations messaging from NPNS says that the new effluent treatment facility will be better than the existing one at Boat Harbour. However, this is not credible because Boat Harbour currently allows all the solids and the worst toxic elements to settle out and for the fluid to cool, often called "polishing off", as it is held for approximately a month before its release into the Northumberland Strait. The new effluent system will attempt to "treat" and cool the effluent in a matter of hours before it is released directly into the marine environment. In private documents and in recent media interviews, NPNS executives have admitted that the effluent is likely to be no better - and could potentially be worse - than what now flows into the Boat Harbour basin (Point C).

Total Suspended Solids (TSS) largely consists of cellulose fibers. Although the document states that 85 to 95% of the lignin, cellulose, sodium sulphide and sodium hydroxide will be removed from the sludge via biological activity in treatment, there is no information provided about the 5-15% which survives treatment - the cellulose. Cellulose fibers are refractory, meaning that they don't degrade quickly or decompose well in water, especially seawater. The registration document provides, in section 5.2.2.9 on Effluent Quality, that the effluent annual average flow will have an anticipated TSS concentration of 48 mg/l of effluent which equates to

a total 3053 kg of TSS per day, i.e., a full dump truck load each day in equivalent tonnage. These fibers have the potential to settle into a deep hole or depression, smothering the bottom and causing anoxia in the underlying sediment. The document hints at this on page 347: "The discharge of effluent containing elevated levels of TSS could also cause a change in sediment quality near the diffuser due to the settlement of suspended sediment, which could cause a change in sediment characteristics such as sand and silt size fractions and/or a change in chemical composition of sediments". The TSS could very likely spread beyond the area near the diffuser due to the buoyant nature of effluent and the likelihood that the effluent plume will reach the surface of the marine water column. This is the very same TSS, known to be harmful to marine life, that NPNS was found to be pumping at a rate of double the daily legal limit into Boat Harbour during the company's 2014 spill on First Nations land.

The insoluble nature of these fibers, the proposed volume of TSS discharge, the potentially wide area of impact and the inability to observe and monitor the effluent stream make this incredibly risky and appear to guarantee a significant impact on the marine environment.

Cumulative Effects: Long Term risk in a Fragile Ecosystem

The Gulf of St. Lawrence is already one of the most highly-stressed marine ecosystems on earth. In a recent study published in the journal Nature Climate Change indicates that the Gulf of St. Lawrence is showing a dramatic decline in oxygen.

A separate study done by DFO and University du Quebec entitled "Man-Made Environmental Changes in the Southern Gulf of St. Lawrence, and their Possible Impact on Inshore Fisheries" states: "Major sources of stress on the Gulf of St. Lawrence ecosystem include climatic changes on one hand and human-induced interferences such as physical modification, pollution and harvesting on the other hand. There are indications that these changes have significant impact on the oceanography, ecology and fisheries of the Gulf. The potential danger to the fishery includes physical, biological and chemical contamination."

This is research that should be covered in effective cumulative effects assessment processes examining marine environments. Northern Pulp's Cumulative Effects research presents a marine "Regional Assessment Area" between Pictou Harbour and Charlottetown to the north, spanning approximately 60 kilometres in an east-west direction. The proponents claim that the majority of the disruption to ocean habitat is likely to take place during the project's construction phase, when the seafloor is to be dredged and laid with a rocky substrate to lay the pipeline and keep it place over the long-term. As for the operations phase, during which the pipe will dump its tens of million litres of treated effluent into the Strait, the report suggest that all concerns related to the quality of the water will dissipate within five metres of the discharge location.

The report claims that "given the likely lack of spatial overlap at this location, significant cumulative residual environmental effects to water quality or sediment quality as a result of treated effluent discharge are not likely." But several studies, as well as ECCC expert testimony before the Prince Edward Island Standing Committee on Agriculture and Fisheries referenced above, tell us that pulp and paper effluent *is* known to be harmful to fish and fish habitat in the majority of tested circumstances. In essence, the substance that Northern Pulp would inject into the Northumberland Strait *would*, undoubtedly, pose a threat to aquatic life - and the assessment document says as much - *but suggests that*, because of dilutive power of the ocean, no great harm should occur in this instance. This simply is not true and this type of outdated Industrial Age thinking, suggesting that, because the ocean is big, it should be able to absorb our waste forever, is the same thinking that now sees the entire planet awash with plastic waste.

In a Northumberland Strait context, the cumulative impacts of over 25 billion liters of toxic effluent flowing into the water every year in perpetuity are potentially catastrophic. The NPNS registration document clearly shows that there will be very little, if any, positive change in wastewater quality with the proposed effluent treatment system and information revealed through the FOIPOP requested showed NPNS suggesting that the effluent could in fact be worse. With a myriad of chemical and nutrient inputs from municipal wastewater systems, industrial operations and agricultural runoff, among others, this is no time to augment present threats to marine life by adding a continuous, high volume stream of toxic pollution into a shallow, low flowing section of the ecosystem. We need our governments and our commercial industries to work together to reduce the inputs already entering into the Strait, and we need to put plans in place to start restoring this natural Maritime treasure, as has been called for by federal studies. If we don't, we are at significant risk of creating contaminated marine habitats and unfishable dead zones in the future.

Pipeline Pathway

The effluent pipeline will go over Pictou Harbour, attached to the causeway across Highway 106 and then in a trench through the Town of Pictou's water supply area, putting both at risk in the event of a pipeline breach or spill. Similarly, the potential for pipeline failure at Caribou Harbour is considerable. These are unacceptable risks.

Air Pollution

In the plan outlined in NPNS's registration document, toxic sludge will be collected early in the effluent treatment process and will then be burned in the NPNS power boiler. Chemicals from this process, including Polycyclic Aromatic Hydrocarbons, Volatile Organic Compounds, sulphur and chlorinated compounds, benzine, cadmium, as well as fine particulate matter will be released. The NPNS registration document speaks virtuously about displacing unspecified amounts of fossil fuels by collecting and burning chemically-laden sludge from the pulping process. It states the sludge will have a 40% moisture content. This will provide no fuel (heat) value and will likely require as much or more fossil fuel to burn. Much worse is the fact that it will actually make the mill's already terrible air emissions problems even worse by burning this toxic sludge in the mill's power boiler which has no precipitator and reportedly malfunctioning/non-functioning scrubbers to "clean" the Sulphur, VOCs and other chemical compounds, and carcinogenic fine particulate matter (PM10 and PM 2.5). The NPNS registration document indicates incineration of up to 20 tonnes of chemically laden sludge per day in the power boiler. The power boiler is very old and has repeatedly failed stack emissions tests. This is a significant public health risk and yet another compelling reason to reject this proposal. Although the provincial Class 1 Environmental Assessment does not specifically require the proponent to conduct a human health risk assessment (HHRA) study, such a study should be ordered by the minister under Environment Act Section 34(1)c or b.

The NPNS registration document acknowledges that there will be additional pollutants released by burning the sludge in the power boiler and that these airborne pollutants will land on nearby "receptors" (e.g. people, animals, land, water, etc.):

"Emissions of combustion gases, particulate matter, and possibly odour from the replacement ETF during operation and maintenance could result in air contaminants that could disperse in the atmosphere to off-site receptors. Additionally, since the project will include the combustion of sludge generated in the replacement ETF for energy recovery and odour control, emissions from the combustion of such sludge in the power boiler during operation and maintenance could disperse from mill stacks to off-site receptors." (Pg. 142)

Air quality testing has been incredibly lax in and around the NPNS mill. A new, robust independent air quality monitoring program should be required of NPNS by the Minister. This should include continuous stack emissions monitoring and multiple remote sensors. This data should be made available to the public in a continuous, real-time feed over the internet.

A sample of some of NPNS's recent air pollution violations:

- In 2014 the mill reported the release of 1,290 tonnes of fine particulate matter — the equivalent of 13 Irving St. John pulp mills in one location.
- Air emissions exceeded limits 4 times in a two year span - March and September 2015, June and December 2016.
- NSE investigation in 2017 as mill exceeded air contaminant emissions limits by nearly 50 per cent in June.
- The mill exceeded emissions 3 years in a row (2015, 2016 and 2017) despite the purchase and instillation of a new electrostatic precipitator on the recovery boiler stack.

Socio-Economic Impacts

Risk to Fisheries and Aquaculture

Despite NPNS's claim that the project proposal's impact on marine life will not be significant, the company's Receiving Waters Study, prepared by Stantec in August of 2017, states, "Among the four potential outfall locations … the [chosen] outfall location provides the *smallest potential long-term cumulative effects* on the fishery and socio-economic environments, and therefore is considered the better outfall location for the discharge of the treated wastewater from the mill." (Conclusion 2.4) Here we see suggestion that NPNS is well aware that the fishery will be adversely impacted in the long term, despite public claims to the contrary. The potential impacts to fish, bivalves, crustaceans, fish habitat and critical spawning areas are outlined above. While the deleterious short term impacts of NPNS's proposed effluent treatment facility on fisheries may be limited to a relatively small area, the long-term effects could still be significant. The Lobster Fishing Area 26A, stretching east-west from Pugwash to Port Hastings and north of Souris, PEI, supports more than 700 licenses at 300 traps per license. This is a marine area worth upwards of $40 million on fisheries alone. The Northumberland Fishermen's Association notes in a position letter that the Strait is one of the "most lucrative habitat and spawning grounds for lobster, crab, scallop, herring, mackerel and groundfish" in the Gulf. Each haul is significant to the fishermen that live and work there and, as such, the long term effects on the larger fishery should be more carefully considered.

Northern Pulp has demonstrated a clear unwillingness to do the work necessary to address these concerns in their environmental assessment registration document; particularly those concerns of the lobster fishermen in the region. NPNS's consultants at Dillon Consulting even went so far as to prompt Northern Pulp via letter in February of 2018, noting the importance of further research on lobster at all of the animal's life developmental stages: "… Conducting research on lobster larvae, and potential alternative to pipe discharge into the Strait needs to be completed to demonstrate to regulators that these were properly considered and stakeholder concerns are being addressed as much as reasonably possible."

In spite of this recommendation, NPNS did not conduct any studies or provide any information on potential impacts over the various life stages of the most important commercial marine species in the Canadian Atlantic, simply dismissing the issue by saying, "It was the conclusion that it is highly unlikely that there will be serious

impact on lobster or lobster larvae given the limited area of potential impact." The assessment goes on to admit that marine studies "have been hampered by both seasonal constraints and by physical opposition and obstruction... The existing environmental conditions and associated potential environmental effects of the project therefore have been defined based on existing available information." Again, we see a standard of care set far too low, in the face of significant risks and potential consequences.

Maritimers and Maritime fishermen have told NS Environment and NPNS loud and clear that this is a risk they are not willing to have foisted upon them; that the social and economic value of the region's fisheries are simply too great. Fishing unions and associations alike have since called, for a federal environmental assessment. At a broader scale, the economic value of Atlantic Canadian seafood production is immense. Fisheries and aquaculture products account for upwards of $3 billion to the Atlantic economy, with more than 15,000 licensed fishing boats and more than 500 aquaculture outfits. The Northumberland Strait is major component of that system, and the Southern Gulf of St. Lawrence has been one of the most productive lobster regions in the country. Today, there are some 700 fishing licenses. The legitimate concerns of the Northumberland Strait fishermen, and Canadian fishermen more broadly, need to accepted and respected.

Reputational Risk to Nova Scotia Seafood Brand

Nova Scotia has an international reputation for producing high-quality seafood from "cold, clean and pristine northern waters". This is particularly true for our shellfish - lobster, scallops and oysters. The reputational risk to the industry if any harvested species becomes contaminated with pollutants is significant - particularly in emerging markets in China and southeast Asia where demand from an expanding middle class is dependent on the "clean and pristine" brand. In this regard it is instructive to recall that the discovery of a single reported case of BSE or mad cow disease in 2003 led to an immediate worldwide ban on all Canadian beef imports which lasted for years and cost the industry billions of dollars in lost sales. Imagine what one contaminated lobster could do the Canadian lobster industry's access to foreign markets. Even the idea of seafood produced in polluted waters could be enough to shut down or seriously curtail demand in sensitive markets like China. This is a serious financial risk that Nova Scotia cannot afford to take.

EAC supports the fishermen.

Tourism Industry

The tourism industry in Nova Scotia is worth $2.7 Billion and growing, creating 40,000 jobs and producing $300 million in taxes. At a regional level, tourism revenue in the Northumberland Shore Region of Nova Scotia is 7.8% of the total tourism revenues translating to $210.6 Million and over 3,200 jobs, generating about $24M in tax revenues. This sector of the economy could be much greater but is hampered by the presence of the NPNS mill.

Tourism operators have reported the length of stay in the Town of Pictou has declined from 2010, an average of 3.3 days to 2017 at 2.5 days. Tourism Operators explain the decline in visitor stays is a direct result of the air and water pollution emanating from the NPNS mill. Allowing the mill to release its effluent into the Northumberland Strait and to increase its harmful air emissions by burning large quantities of toxic sludge will only make things worse for this industry. Tourism operators in western Cape Breton (Inverness County), along the south coast of PEI and the New Brunswick coastline of the Northumberland Strait are all at risk of impacts from the proposed discharge of large volumes of effluent into the marine environment.

EAC supports the tourism operators.

Indigenous opposition

It is important to note that all of the Mi'kmaq Chiefs in the three Maritime Provinces are opposed to piping the NPNS mill's effluent into the Northumberland Strait. Chief Terry Paul identified the mill's proposal for a new effluent treatment plant as the top issue raised by Mi'kmaq leaders in their annual meeting with Provincial Cabinet in December 2017. "The first consideration is the environment" he said. "We want to ensure that whatever is done to mitigate the effluent there isn't detrimental to the fishery". He stated clearly that the chiefs cannot support the NPNS effluent pipe plan. Chief Andrea Paul of Pictou Landing First Nation has been unequivocal in stating her communities firm opposition to the proposed new effluent treatment system. "The effluent discharge is in the Northumberland Strait and for that we are opposing it" she said in July 2018. "We do not want this pipe in our waters. We need to protect our resources. All of us have an inherent duty to do that".

EAC supports the Mi'kmaq.

Unwillingness to Explore Alternatives

The pulp mill in Pictou County has a long history of putting Nova Scotia's environment and citizens at risk. Despite five years to find a suitable alternative to the Boat Harbour treatment facility and taking the opportunity to improve their environmental performance, NPNS simply offers one single option: to pollute a different area, this time spreading the potential impact much further. The registration document has been carefully tailored to reach the NPNS's preferred outcome of pumping the effluent into the sea. In preparing the document the consultants, appear to have relied almost exclusively on information provided by NPNS. There is no evidence of serious independent analysis of the options, assumptions or conclusions in the report. The Ecology Action Centre strongly disagrees and believes that NPNS could do much to 1) reduce the toxicity of their effluent by improving internal process inside the mill and 2) negate the need to dispose of their effluent into the environment at all by modifying their production process (i.e. eliminate chemical bleaching) and installing a closed-loop system.

It is clear from NPNS's registration document that the scope of exploration of alternative options was deliberately narrow and entirely restricted to finding an alternative dumping site for the effluent. All other options to reduce or eliminate the mills liquid pollution output are summarily dismissed early in the registration document, abandoning any further consideration or research for better options. On its project website, NPNS confirms this: "At the onset of the design phase a closed loop (zero effluent) treatment alternative was immediately ruled out as it is not an option for Northern Pulp. A closed loop system does not exist anywhere in the world for an elemental chlorine free (ECF) bleached kraft pulp mill. The concept is not technically or economically achievable." This is consistent with NPNS's long-held public position that only a pipeline into the Northumberland Strait will work. NPNS says the technology does not exist to close their loop. They are lying by omission.

NPNS could install and run a closed-loop system if it simply changed its production process and stopped bleaching their semi-finished kraft pulp product prior to shipping it to their Asian parent company. The result would be a light brown fiber product rather than a bright-white one. If the parent company wished to bleach some or all of the kraft pulp during its subsequent product production processes (making tissue, napkins, diapers, etc.) they could easily do so at their end. Another workable alternative would be to retool the NPNS mill to use peroxide and ozone instead of chlorine dioxide to whiten their kraft pulp and thus become a Totally Chlorine Free (TCF) mill.

The truth is NPNS could change its process and install a closed loop system but they have chosen not to. They admit as much in their registration document (Project Alternative 3: Change the NPNS Mill Type and Make a

Closed Loop System, Pgs. 25-26), stating the reason for not doing so is that it is “market prohibitive”, not that it is technically impossible. Their justification for not doing so is cost: “NPNS would not remain competitive due to high wood and electricity costs” and that “NPNS must continue to operate by producing NBSK to be economically viable”. They admitted that “Production of a different type of pulp can allow operation using closed loop systems.” But that “NPNS would not be economically viable with a different product”. Although NPNS says changing their product process is “not economically viable”, they provide no proof for these claim.

Notwithstanding their refusal to seriously consider altering their process and implementing a closed loop system, before the NPNS mill starts pumping their effluent anywhere they should first be required to improve the inside performance of their very old mill in order to significantly improve the quality of the effluent before it is sent for secondary treatment. In industry parlance this is called “tightening up the loops” inside the mill prior to the effluent treatment process. The mill employs very old (1960s era) technology. There are three specific areas that need to be modernized before sending effluent into a secondary treatment system, regardless of where the effluent is subsequently dumped. They are: #1 Optimize brown stock washing, #2 Install an oxygen delignification system in the bleaching plant and #3 Implement fail-safe systems to ensure against process upsets into the effluent treatment system. Process upsets can come from overflows of brown stock, bleach and/or black liquor.

It’s important to point out that with regard to #2, NPNS has previously said they would be installing an oxygen delignification system which would result in a 30 to 40% reduction in chlorine dioxide bleaching chemicals and thus much “cleaner” effluent. That oxygen delignification system is now missing from NPNS's registration document.

It’s also important to highlight why NPNS should be required to build in effective fail-safe systems to minimize and contain process upsets whereby the system becomes overloaded with pulping chemicals and shuts down the biological activated sludge (BAS) treatment process. In brief: NPNS has a history of frequent process upsets with its current effluent treatment system in Boat Harbour. When this happens the biological agents (bacteria, fungi and protozoa) that are used to consume organic pollution from the effluent prior to release are killed and the process stops working. In the Boat Harbour lagoon, the untreated effluent can be contained at an early stage while the system is re-inoculated with replacement biological agents so treatment can be resumed. This can take several days. In the event of black liquor or other chemical spills into the proposed new effluent treatment system, the biological agents will be killed and the system will stop functioning as it’s supposed to. In the registration document, NPNS says it plans to build a 35 million liter raw effluent spill basin that, assuming optimum conditions, will be sufficient to contain 10 to 13 hours of effluent diversion in the event of process upsets (pg. 42). That means only half a day’s worth of effluent can be contained while they try to fix the problem. But process upsets often take much longer to fix than half a day. Therefore the risk of potentially large volumes of untreated effluent by-passing the new effluent treatment system and flowing directly out into the marine environment is very high as their proposed spill basin will be too small to contain effluent volumes greater than half a day’s output while NPNS works to restore the biological agents to sufficient levels to function again.

NPNS has repeatedly minimized serious concerns about their effluent treatment plan. Vague assurances through the registration document with phrases such as ‘no significant residual environmental effect predicted’ are simply not credible, particularly in light of the vast evidence of ecosystem destruction committed at Boat Harbour. With an effluent leak only months ago in October 2018, which was discovered by a citizen walking in the vicinity of the mill, and another in June 2014 that released 47 million litres before detection, public trust is at an all-time low. Attribution of pollution in the Northumberland Strait will be challenging, ensuring that the province of Nova Scotia will have a very difficult time seeking remediation for damages. Fastidious monitoring will be required to intervene as quickly as possible and ideally this monitoring would be administered by an independent body to ensure compliance.

Conclusion

The Ecology Action Centre strongly recommends that the Minister of Environment reject NPNS's effluent treatment facility proposal as outlined in their registration document. The document fails to provide the Province with the required information to assure itself and all Nova Scotians that their proposed effluent treatment facility would be safe for the community or the environment. All evidence points to the fact that this effluent treatment facility will cause at least as much pollution as the levels at Boat Harbour, if not more, and this time the pollution will be spread over a far greater area with even less ability to contain and repair that damage in the future. It is also clear that the burning of large amounts of toxic sludge in the power boiler will make the mill's already terrible air emissions even worse. The claims by NPNS that there will be no impact of any kind is not credible and they have failed to provide evidence that this even possible. It is unconscionable of NPNS to ask, nay, demand that Nova Scotian's accept all the risks and harms so an ancient, highly-polluting pulp mill can continue operating for a few more years.

NPNS has shown a consistent sense of entitlement, often operating outside of the rules and boundaries which exist to protect our environment. NPNS even made a request to begin building elements of its proposed new effluent treatment system in mid-2018, well before submitting its proposal for environmental assessment. The sheer audacity of this request demonstrates a corporation that fully expects Nova Scotia to continue to bend to their wishes, regardless of the impacts. Now that we are within a year of the January 31, 2020 shut down date for the Boat Harbour effluent treatment system, the corporation has requested an extension to continue polluting Boat Harbour, citing a lack of time to get an alternative in place. Complying with this request would require repealing that legislation and would be an unforgivable violation of the faith of the Pictou Landing First Nations community and to every other Nova Scotian who is counting down the days until January 31, 2020.

It is time for this province to stop operating with a methodology of privatizing our shared natural resources for private profit while socializing the enormous risks and costs. Nova Scotian taxpayers will long be paying for the damage that has already been done by the pulp mill at Abercrombie Point in Pictou County. The investment to create the new pipe, a piece of infrastructure which will cost an enormous amount and likely to be charged again to the taxpayer, is making a commitment to allow this mill to continue discharging toxic effluent into our environment for many years to come. That is unacceptable. The Minister should reject this project outright. Failing that the Minister must, at the very least, order focus reports in a number of areas where information is lacking, including the composition of the effluent, baseline studies on lobsters and other marine species, baseline benthic surveys of the bottom of Caribou Bay, plans for air pollution controls and monitoring, etc. The minister should also order the mill to upgrade its internal processes and equipment to reduce its already substantial air and water pollution levels regardless of if or where they might send their effluent. But at the end of the day the Minister must not make a bad situation worse by allowing another place to be fouled and one that can never be cleaned up.

In closing we cite Premier Stephen McNeil's wise words at the annual meeting of Nova Scotia Cabinet and Mi'kmaq Chiefs on December 14th, 2017 in Millbrook: "*It has never been our government's intention and never will be our government's intention to clean up one environmental problem and move it somewhere else*."

And that is the right answer. No pipe.

Respectfully submitted,

Wilderness Coordinator
Coastal Coordinator
Marine Conservation Officer

Subject: Proposed Project Comments
Date: March 9, 2019 10:08:40 PM

Project: replacement_effluent_treatment_facility_project Comments: To Whom It May Concern: I am opposed to this project on jurisdictional, environmental, and human health grounds. First of all, it should be undergoing the more extensive federal environmental assessment, as t it involves probable deleterious effects on nearby oceans, navigable waters, commercial fisheries, fish habitat, and the health of residents of the Pictou Landing First Nation. All of the above are primarily federal responsibilities. Proponents of the proposed effluent pipe claim that a closed loop system of bleach kraft effluent is not viable. This assertion needs a much more rigid analysis by an independent party. I am opposed to further dumping of effluent, containing toxins and nutrients, resulting in increased chemical and biological oxygen demand in the receiving waters. Where are the studies of potential long-term toxicity of the proposed effluent to marine life, particularly to species targeted by commercial fishers? There are none. Instead, we are told that the pulp mills effluent is too toxic to be reused within the mill. The current proposal is full of models, assumptions, and simulations yet in the final analysis we cannot tell what will happen to the Northumberland Strait marine environment and its fisheries and our health should the toxic effluent pipe be approved and constructed. Approval of the proposed project would constitute a giant leap of faith, a major uncontrolled experiment with no backstop. It is contrary to the precautionary principle and should be rejected in its entirety. Name: MD Email: @ns.sympatico.ca Address:

Subject: Northern Pulp Replacement Effluent Pipe
Date: March 9, 2019 10:45:22 PM

Please accept this as my reasons for requesting a rejection of the current proposal submitted by Nortern Pulp for their replacement of Boat Harbour.

1. They have submitted a plan to pipe effluent at several degrees higher than normal receiving water temperatures into a vital ecological and highly stressed area of our ocean, that cannot endure further disregard.

2. They have submitted a plan to pipe effluent containing one ton of solids per day into a vital ecological and highly stressed area of our ocean, that cannot endure further disregard.

3. They have submitted a plan to pipe effluent containing toxins, including dioxins and furans, into a vital ecological and highly stressed area of our ocean, that cannot endure further disregard.

4. They have submitted a plan to pipe effluent that is worse in character and quality than that which currently leaves the Boat Harbour estuary, by their own account, into a vital ecological and highly stressed area of our ocean, that cannot endure further disregard.

5. They have submitted a plan to pipe effluent containing unknown levels of toxins, by their own account, into a vital ecological and highly stressed area of our ocean, that cannot endure further disregard.

6. They have submitted a plan to pipe effluent into a vital ecological and highly stressed area of our ocean, that cannot endure further disregard, that has twice been rejected when submitted previously. Which also leads to the value for tax payer dollars supplied to Northern Pulp, to recycle this twice rejected plan. It also casts doubts in every claim about about tight time lines. Doubts that cause anger. Was this recycled plan worth $6 Million?

7. They have submitted a plan to pipe effluent through a well field and watershed, essential to the local homes and broader community for water and then release the effluent into a vital ecological and highly stressed area of our ocean, that cannot endure further disregard. How many leaks and ruptures in this company's pipe does it take for this idea to be be deemed blatantly insane?

8. The proposal includes a request to give the company an additional 21 months to build said pipeline..... they had 6 years to develop a plan, and seek approval. They waited until 2018 to submit a recycled and twice rejected plan.

9. Part of their current Industrial approval, issued in 2015, included the requirement for flow metre to be installed on each end of the effluent pipe, to monitor for leaks. This has never been done. They are in violation of their current industrial approval.

10. How does one test the output on the diffuser end of the pipeline? As in, toxins, temperature, etc.

11. At a time when food security is paramount, and water resource is crucial, this mill using the volumes of fresh water daily to dilute their poisonous sludge to "meet" regulations, while risking a major food source, not to mention an economic driver in the province, is inherently unlawful.

12. The mill has issued varied statements in the media, in their proposal and in court documents about the jobs that will be impacted by a closure. I would advise that the legally binding numbers are likely the most accurate at less than 1,000, and would hope that all the noise and bolstered confusion over the future of Nova Scotia's forest industry could be cleared up with another recent bit of insight regarding PHP importing wood and wood chips from NB and Quebec at much higher rates than NS forestry companies are being paid by Northern Pulp.

13. How many fishery jobs will be impacted by this proposal?

I have many other concerns, but I feel these are fairly easily understood and are the ones that stand out for me.

Regards,

Please find attached my comments on the Environmental Assessment of Northern Pulp's proposed Replacement ETF.

I would appreciate acknowledgment of receipt of my submission.

March 9, 2019
Re: EA Northern Pulp Replacement Effluent Treatment Facility

Dear Minister Miller,

I live in Pictou County, overlooking the River John, as it flows into the Northumberland Strait. I have spent the last 16 months educating myself about what Northern Pulp's proposed new ETF could mean for the Strait, for those who fish its waters, enjoy its beaches, value its complex ecosystem and love its beauty.

In that time, I have learned from fishermen many things I did not know before. I learned that lobster thrive on the rock crab that are plentiful in Caribou Harbour, that scallops release 6 million eggs, but only one develops into a scallop, that small changes can lead to marine life leaving an area where they were previously plentiful. I have learned to appreciate these waters in a way I did not before. Fishermen understand ecosystems, that the smallest to largest of marine life, plant and animal, depend on each other and the conditions they live in. I am in awe of the detailed knowledge that fishermen have of the waters, tides, currents, bottoms and creatures where they fish, because their livelihoods and their safety and the safety of their crews depend on this knowledge.

I also learned that fishermen make changes every year at their own expense in order to protect the future of their industry and to protect the environment. One example is voluntarily increasing the carapace size of lobsters which they take, which means a smaller catch in the short term but a healthier and more productive population in future years. Another example is the changes in quota which can be announced suddenly by DFO, and may mean a 50% or more decrease in allowable catch from one year to the next. Or, as last year, the closure of the lucrative snow crab fishery for part or all of a season in order to protect Right Whales.

This is the reality of life for fishing families. They do not have an automatic entitlement to make maximum profit – their profits are constantly balanced by the need to protect the environment and the future of the fisheries.

Lack of adequate public consultation
I have spent the last month immersed in 1700 pages of documentation which the public was given only 30 days to read, understand and respond to. I believe that this was not an adequate process of public consultation, especially as no Open Houses were conducted on the proposal including the new route, new outfall location, and many differences in technology, including a missing oxygen delignification system.

Lack of critical information
In those 1700 pages there are many issues to comment on. Among other issues, there is the lack of critical information on effluent composition and on the majority of the VECs, the absence of water analyses from Caribou Harbour, and the use of baseline water data from Pictou Harbour as "proxy"-- which Northern Pulp itself admits is more polluted than Caribou

Harbour -- and the very strange use of an HHE report based on a human health risk analysis of a mill-that-never-existed. I would have thought those omissions would have led you as Minister to refuse registration of the project documents as incomplete. But that did not happen, so I would hope these serious omissions will stand as red flags to your department now.

A vibrant ecosystem

Northern Pulp either exhibits no understanding of ecosystems, or does not want the Minister to understand that Caribou Harbour is a complex and vulnerable ecosystem full of life.

There is one photo which I found particularly striking.

Figure 8.12-1 on page 363 is a still photo of the bottom of Caribou Harbour. The caption states that it is devoid of macro flora and macro fauna. What is odd is that, according to Graham Edgar, Professor of marine ecology and conservation science at the University of Tasmania macro fauna are "the small invertebrates that are just marginally too small to see with the human eye." So macro fauna would not be seen -- how can the author conclude it is devoid of macro fauna?

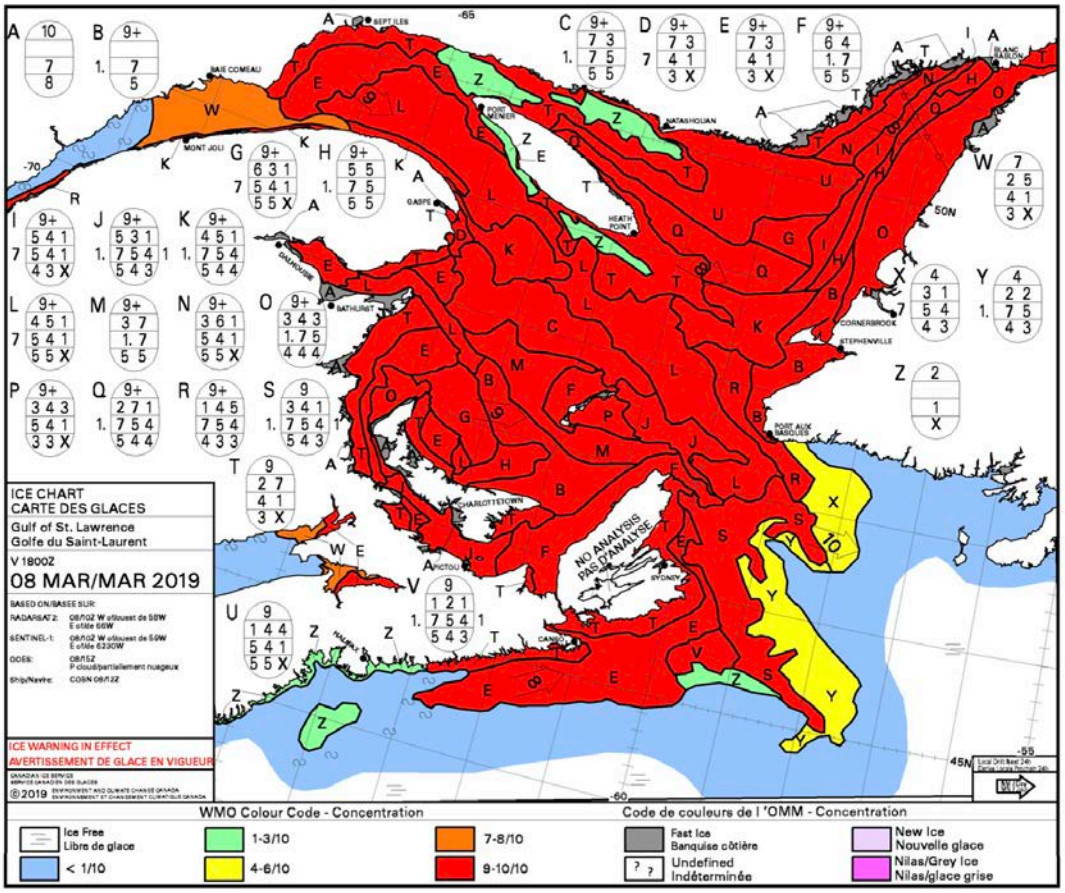
The purpose of the photo seems to be to imply that the bottom of Caribou Harbour is devoid of life. Nothing could be farther from the truth. Under that sand there could be a thriving population of bar clams, rock crab, and other species for whom Caribou Harbour serves as habitat and nursery. Floating in the water there could be many life forms, from plankton up, in various life stages, all of which are critical to a healthy ecosystem.

Ice

I would like to point to the high likelihood of ice damage to the pipe, and the inability of Northern Pulp to repair that damage in a timely way, even if it were identified in a timely way.

Northern Pulp only looks at the possibility of ice damage to the diffusers, which is dismissed as being taken care of by normal tides and currents. If that were true, diffusers would not be required. And differences of diffusion under ice conditions are ignored.

But an even greater issue is the risk of damage to the pipe itself in the shallow waters of Caribou Harbour. The proposed outfall location is in a “hole” 20 metres deep, in a narrow channel. The depth of the majority of Caribou Harbour, both closer to shore and on the far side of the proposed diffuser location, is from 0 to 8 metres deep. Damage to the pipe before it reaches the diffuser would take place in a shallow area, where sufficient flushing would not occur. The result of damage to the pipe could damage the entire rich ecosystem of Caribou Harbour for many decades. This is not a small possibility, it is a likelihood, according to fishers and a master diver I have spoken with, all of whom have watched the force of ice in the area for years and have made their own submissions to this EA.



In 10.4.4.1, Northern Pulp states, “Upon detection of any marine outfall pipe damage or diffuser fouling, repairs would be promptly performed.” **This is impossible.** Ice locks in Caribou Harbour for four months or more in the winter. The ice map of March 8, 2019 gives an indication of the thickness of ice in the area as well as the presence of fast ice in the Caribou area. It is during these winter months when the likelihood of damage to the pipe itself or diffusers, is greatest.

The Minister should consider the issue of likely ice damage to the pipe as establishing a likelihood of harm which is not mitigable. The force and duration of ice cannot be changed. The vulnerability of a pipe in those conditions is established in other submissions. The danger to Caribou Harbour is established by the fact that Northern Pulp did not choose an outfall location in the Harbour itself.

As well, the Minister should be warned by this casual reassurance of timely repair which is clearly impossible for 1/3 of the year. The Minister should take this example as a caution in relation to Northern Pulp’s many other breezy reassurances that no harm will be done or that it is mitigable, with no detail provided.

Mercury risks

Finally, I would like to raise the issue of the known presence of mercury contamination from the Canso Chemicals plant in bedrock and in 1990s era “secure landfills”, on the site adjacent to Northern Pulp very close to where the plan is for components of the proposed ETF to be set into the ground at a depth of 7 feet, requiring digging to that depth or more.

This issue only came to public attention several days ago through the release of information from the 2000 Decommissioning Report of Canso Chemicals. This raises complex risk issues which the Minister must insure are fully investigated and evaluated in the public eye, not behind closed doors, to determine whether the construction or operation of the proposed new effluent treatment plant could increase or hasten release of mercury in soil, air or water. Given that the previous elemental chlorine process used at the mill would have involved mercury, the attention given to Canso Chemicals raised questions for me as to whether the Northern Pulp site itself might also have some mercury contamination that could be released during construction or operation. These are issues that must be fully examined prior to approval of this project.

Northern Pulp’s summary no-harm-ever-to anything chart is not credible

Northern Pulp’s summary chart says that under no conditions, normal operation, malfunctions, accidents, will any significant residual harm be done to anything. That conclusion is not credible.

We can look at dead zones and environmental degradation attributed to pulp and paper mills in other locations or we can look in our own back yard to question that sunny conclusion. For almost three decades now, Boat Harbour Basin has been the Receiving Water for treated pulp

effluent from Northern Pulp. The effluent entering Boat Harbour meets PPER regulations, but Boat Harbour is far from a healthy, or even recovering, ecosystem today.

Northern Pulp's registration documents mock the Environmental Assessment process. Northern Pulp may as well have said: "We don't need to provide any hard information about the effluent, we don't need to do any studies, decades old data from other locations are good enough, we don't need to seriously consider the harm this project might do, and there is no need for the public to have the required information and scrutinize it to point out potential risks. We dare Nova Scotia Environment not to approve our application."

The proponent has addressed the risks of this project with a lack of seriousness. The proponent has provided no proof that harm will not be done. The proponent has neglected to provide the most basic data and science, e.g. no effluent composition, no water analysis of the outfall location, no lobster larvae studies, no evidence to even show that the effluent will meet federal regulations or provincial standards.

The Minister cannot make a science-based decision to approve this project, as there is no science on which to base a decision. The proponent's past record of poor compliance with regulations and a proven inability to identify leaks in a timely manner, despite being required in their Industrial Approval to have a system in place that that would insure timely detection of leaks, adds significantly to the risk of this proposed project.

I believe the Minister has grounds to reject this proposal on the basis that it has a likelihood of adverse effects or significant environmental effects, and I urge you do so. If the minister approves this project now, she will be setting a very dangerous precedent and encouraging other proponents to follow a similar path, which is inconsistent with the Environment Act.

If the Minister chooses not to reject this project, at the very least she must not accept Northern Pulp's proposal to provide future information to NSE behind closed doors, away from public examination and input. The minister must require a process which allows for full public examination and input into the many issues for which data has not been provided. That would require the Minister to order a full environmental assessment report.

Sincerely,

March 9, 2019

To: Nova Scotia Environment:

The Nova Scotia Chapter of the Canadian Parks and Wilderness Society (CPAWS-NS) has reviewed the Environmental Assessment Registration Document prepared by Dillon Consulting for Northern Pulp Nova Scotia Corporation for the proposed Replacement Effluent Treatment Facility. This proposed undertaking includes a 15.5km long pipeline, which is intended to empty into the marine environment of the Northumberland Strait.

CPAWS-NS is concerned about this proposed undertaking and the impact it could have on the environment and the inshore fishery. We are also concerned about the rushed manner in which this Environmental Assessment Registration Document appears to have been prepared.

As an organization, we had intended on providing a thorough and detailed review of one aspect of the environmental assessment review, dealing solely with "wetlands". I have a Ph.D. in wetland ecology from the Wetlands Research Centre at the University of Waterloo, and have provided advice to the Nova Scotia government for the development of a provincial wetland policy. Unfortunately, so little information has been provided within the Environmental Assessment Registration Document for the proposed Undertaking dealing with "wetlands" that CPAWS-NS is unable to carry out a proper review. In fact, it is shocking just how little information is provided.

The consultants acknowledge the deficiency in the information provided for the wetland assessment, stating the following:

> *"It should be noted that fall 2017 to summer 2018 field investigations were undertaken at the replacement ETF footprint area and surrounding area, but as an alternate pipeline route was selected in the fall of 2018 (see Section 5.3) and due to the fall/winter*

> *timing of route selection, only a preliminary reconnaissance visit of the pipeline footprint area was undertaken" (Pg. 223)*

That "preliminary reconnaissance" consisted of a single day of fieldwork, undertaken on December 3, 2018. That's one day of fieldwork, undertaken at a time of year when vegetation surveys could not be completed. This is appalling in its deficiency. I'm actually surprised it was put forward in such a condition.

The Environmental Assessment Registration Document goes on to say that the wetlands were assessed using a "desktop review".

> *"Wetlands outside of the replacement ETF footprint area (i.e., along the pipeline footprint area) were assessed primarily via a desktop review with a preliminary field reconnaissance visit." (Pg. 225)*

Sorry, but a "desktop review", combined with a single day of reconnaissance fieldwork undertaken at a time of year when a proper assessment cannot be completed, is absolutely unacceptable. They state on Pg 224 of the report that part of their desktop review actually involved using Google Streetview.

The consultants state that a "significant portion" of the study area has "not been surveyed in detail for wetlands":

> *"The proposed location of the effluent pipeline changed following the completion of the wetlands program for the ETF footprint area during the summer of 2018. As such, a significant portion of the PFA (i.e., the pipeline footprint area) has not been surveyed in detail for wetlands." (Pg. 231)*

That is an absolutely outstanding statement for a Proponent to make in an Environmental Assessment Registration Document, that a significant portion of the wetlands in the study area has not actually been surveyed in detail. Astonishing.

The Proponent goes on to admit that the wetland delineations could not be completed because it was "too late in the growing season to accurately delineate wetland boundaries or accurately identify plants."

> *"Full delineations and evaluation of wetland functions for the wetlands adjacent to the pipeline footprint area was not possible since the revised alignment for the pipeline was only defined in the fall of 2018, when wetland delineation/functional evaluation would have been uncertain (i.e., it was too late in the growing season to accurately delineate wetland boundaries or accurately identify plants, especially SAR and SOCC)."* (Pg. 232)
> (SAR = Species at risk; SOCC = Species of Conservation Concern)

Although the Proponent says it was "not possible" to have completed the wetland assessments, we find that to be rather disingenuous. The Proponent has had a lot of time to prepare for this environmental assessment, yet has made big changes only months prior to submitting the Environmental Assessment Registration Document. Poor planning on their part does not constitute an emergency on anyone else's part. A more prudent course of action would have been to delay registering the proposed Undertaking until the required wetland

evaluations could have been completed. At present, the Province of Nova Scotia has insufficient information about potential impacts on those wetlands to be able to make an informed decision on this environmental assessment.

The deficiencies in the wetlands review are even more concerning, considering that the proposed undertaking occurs in an area with numerous wetlands. That "desktop review" alone identified 24 wetlands within the study area, including 11 swamps, 4 bogs, 3 fens, 2 marshes, 1 salt marsh, 1 wet meadow, and 2 vernal pools. Detailed on the ground assessments could identify additional wetlands, given the density at which wetlands seem to occur near this proposed pipeline route. In an area of elevated wetland density, you'd think that the Proponent would have been even more careful in ensuring that the required wetland assessments were completed.

Detailed field surveys appear to have only been carried out at 2 of the 24 identified wetlands. The section on wetlands in the Environmental Assessment Registration Document provides a lot of information about wetland type and function, but hardly any of that is site-specific information for wetlands actually occurring within the study site.

I would like to review the detailed field assessments for every one of these wetlands. I'd like to review what species are found there, how the ecosystems change spatially, and what is the nature of the wetland edge condition. I'd like to review how the hydrology may be impacted by this proposed undertaking, and to assess how the fieldwork was set up to ensure objectivity. But, I cannot, because the majority of the wetlands in the study site simply have not been assessed on-the-ground, so that sort of information is unavailable for review.

Despite the lack of evidence presented, and despite only carrying out a single day of fieldwork where no real data was generated, the Proponent reaches a rather firm conclusion that the proposed undertaking will not impact wetlands. The report states the following:

> *"With the proper implementation of proposed mitigation measures, impacts to wetlands as a result of construction of the project are not anticipated to be significant." (Pg. 240).*

I simply cannot see how anyone could reach such a conclusion about wetlands from the paltry amount of data provided. It is not okay for a Proponent to seek environmental approvals now, without having completed the necessary work, under the promise that it will be done at a later date, after approvals are already received. That's not how environmental assessments should work.

Using just the limited review of the wetlands portion of the Environmental Assessment Registration Document alone, and disregarding any other potential problems with this project and impacts on the environment, the Province of Nova Scotia cannot, in good conscience, approve this project as currently submitted. Seeing just how deficient the report is for wetlands gives me serious concerns that other sections of the Environmental Assessment Registration Document are similarly deficient.

CPAWS-NS respectfully requests that the Minister of Environment refer this proposed Undertaking to a Full Class 2 Environmental Assessment, so that a proper environmental assessment can be carried out. We also respectfully request that the provincial government

contact the federal government to initiate a Federal Environmental Assessment for this proposed Undertaking.

Thank you for your consideration

Re: Comments on the Northern Pulp Nova Scotia Corporation's proposed Replacement Effluent Treatment Facility (ETF) Project

March 9, 2019

To whom it may concern:

Please find below our comments regarding the Northern Pulp Nova Scotia Corporation's proposed Replacement Effluent Treatment Facility (ETF) Project.

We recommend that the Minister of Environment reject this project because it will cause adverse and significant environmental effects that cannot be mitigated. We are also deeply concerned that no federal impact assessment has been performed on the proposed project, since the project will result in transboundary impacts on fish, fish habitat, fisheries, seabirds, and endangered species. Without federal impact assessment, this process cannot fully assess the impacts of the proposed project.

The issue of pollution from Northern Pulp and its predecessors has negatively impacted the environment, health, and social fabric of Pictou County and the region for decades. It is both a literal and figurative toxic legacy of half a century of environmental racism. Allowing continued pollution of the environment and, in particular, allowing continued negative impacts on indigenous communities via this project would impede our responsibility to engage in reconciliation and our obligation to uphold the UN Declaration of the Rights of Indigenous Peoples.

Upon rejecting the proposed project, we recommend that the Minister, with leadership from Nova Scotia's Premier, Mi'kmaq leaders and elders, and federal representatives proceed immediately to work with Pictou Landing First Nation and surrounding communities to develop a sustainable development plan for the region.

Sincerely,

National Programs Director

1. EA Registration document inadequately assesses the sensitivity of the proposed receiving environment for effluent: the Northumberland Strait in the Southern Gulf of St. Lawrence.

The Gulf of St. Lawrence is a semi-enclosed sea that is vitally important to thousands of marine species, including endangered whales and fish. Coastal communities and renewable industries such as fishing and tourism rely on this productive but threatened ecosystem.

The EA registration document fails to incorporate the vulnerability of the Gulf, and in particular, two recent findings on its vulnerability:

1. Impacts of climate change altering ocean currents and creating hypoxic conditions. Researchers found that the Gulf of St. Lawrence will be impacted by these effects more than any other marine ecosystem on the planet (Rapid coastal deoxygenation due to ocean circulation shift in the northwest Atlantic. *Nature Climate Change*. 8: 868–872. https://www.nature.com/articles/s41558-018-0263-1); and
2. Department of Fisheries and Oceans scientists have warned cod in the Southern Gulf are on the verge of extirpation (Continued decline of a collapsed population of Atlantic cod (*Gadus morhua*) due to predation-driven Allee effects. *Canadian Journal of Fisheries and Aquatic Sciences*, 2019, 76(1): 168-184, https://doi.org/10.1139/cjfas-2017-0190).

Continued stressors on this ecosystem, such as the release of large volumes of warm effluent containing nutrients and pollutants will contribute to further degradation of this ecosystem.

2. Risks of mercury contamination inadequately assessed

The EA Registration document fails to identify or assess impacts of construction and operation of the proposed treatment facility near an existing mercury waste dump and mercury contaminated soil.

According to research unearthed by Joan Baxter and published in the *Halifax Examiner*, a mercury containment site and mercury contaminated soil are present at the proposed effluent treatment site (Northern Pulp's environmental documents: missing mercury, a pulp mill that never was, and oodles of contradictions. Mar 5, 2019).

The EA document fails to evaluate the risks associated with disturbing this contaminated soil and mercury containment site on the environment, human health and local fisheries.

3. Information on pollutants (including heavy metals, dioxins, and furans) contained in effluent to be released into the environment is inadequate

The EA does not identify amounts, concentrations and make-up of pollutants (such as heavy metals, dioxins, furans) being released from the proposed treatment facility. On a precautionary basis, the assessment should identify the various potential pollutants to be released, the range of possible concentrations, and means taken to ensure these remain a safe levels. Instead, the EA lists potential pollutants but does not evaluate the range of possible effluent characteristics. As a result, the risk to the environment and human health are not adequately assessed.

A study performed by the Mi'kmaq Conservation Group and sampling undertaken by Nova Scotia Environment after the 2014 spill of effluent from a pipeline leak indicate that dioxins, furans, and mercury

are still present in effluent released by Northern Pulp. This research is absent from the document's Human Health Evaluation (Section 9.0), and should be included in evaluating risks.

Complete information on pollutants to be released from the pipe (identity of pollutants, range of concentrations and seasonal variability) are not adequate to assess effectiveness of mitigation measures proposed or risks to environment and human health.

4. EA process has allowed inadequate time and capacity for consultation

The time and capacity provided to experts, stakeholders, and community members to engage in this environmental assessment process has been inadequate to fully assess risks.

Subject: In support of Northern Pulp"s EA application
Date: March 9, 2019 11:47:18 PM

I am writing in support of the Environmental Assessment application submitted by Northern Pulp for its new treatment facility.

A lot has been said about Northern Pulp and its impact on the local community. I stand in agreement with many, including Unifor, that Boat Harbour must close and be cleaned up to respect Pictou Landing First Nations people and their land. I also know there are many positives about having 300 good-paying jobs in Pictou, supporting thousands more across Nova Scotia, particularly in rural communities.

The Nova Scotia Environment Act is an essential piece of legislation designed to protect our shared environment and guide our economic development. The Act rightly spells out its purpose through a set of principles for sustainable development that should guide its application, including:

------> The linkage between economic and environmental issues, recognizing that long-term economic prosperity depends upon sound environmental management and that effective environmental protection depends on a strong economy.

In this situation, science should determine the best path forward. Nova Scotia, along with the rest of Canada, has among the highest global standards for environmental stewardship in the forestry sector.

The job of government and every person we elect to represent us in government is to find the best way forward when there are many competing and sometimes opposing interests. Communities across Canada manage to find a fair balance where good mill jobs coexist with a prosperous fishing industry and thriving communities.

We can and must find this balance for Pictou. There is a lot at stake: jobs, the environment, and respect for First Nations. We can and must find a solution that supports all three.

Thank you.

March 8, 2019

The Hon. Margaret Miller
Minister of Environment
NS Environment
Box 442
Halifax, NS B3J 2P8

Minister Miller,

To me this Review is about the environment and the environment only My presentation is based on quotations from studies, positions papers and press releases from Canadian government Institutions. It is not about what I think. Or jobs. It's about the reality that the world we are living in today is changing rapidly due many sources of pollution.

The first crisis is the DE oxygenation of the Gulf or St. Lawrence (Northumberland Strait) water. a "In the Gulf of St. Lawrence, Oxygen in the lower depths has dropped by 55 per cent since 1930. We feel this issue has to be looked at and deserves more attention," said Denis Gilbert, one of the 22 co-authors and a Scientist with the Department Fisheries and Oceans. The Gulf of St. Lawrence is rapidly losing Oxygen,faster than almost any other marine ecosystem.

Acidification, mostly caused caused by burning fossil fuels is corroding and preventing formation of shells. The increased acidy will lower the saturation state of the waters with respect to calcite and aragonite and likely affect the ecology of carbonate-secreting organising such as coccolithophores, foraminifera, pteropods, mollusks, crustaceans,echinoderms, gastropods and corals.

The Canadian Journal of Fisheries and Aquatic Sciences stated" Their is a high probability that Atlantic Cod will be Extinct in the Southern Gulf of St. Lawrence by mid century, even with no commercial fishing". Other finfish such as turbot, wolfish and snow crab are listed along with other less known species.

"It started off as a bit of a dip, but then it got more profound" says Pierre Pepin, a senior researcher with the Department of Fisheries and Oceans in St. John's Newfoundland. "we're looking at values that are 50 per cent of what we saw five years ago. that's a substantial

decline”.”The tiny organisms live near the oceans surface and underpin the entire marine food web, feeding the smallest and largest of creatures that call the ocean home. Small but mighty, they are what makes life on Earth possible.

In the Canadian Journal of Fisheries and Aquatic Sciences an article “Linking Zooplankton assemblages with oceanographic zones in an Atlantic coastal ecosystem” states that “Shallow (5- 35 metres water) coastal waters, with their proximity to human populations, are likely to experience greater changes to ecosystem structure and functions from climate change and human impacts than offshore waters. Concerns of declining fisheries landings and deteriorating habitat quality in Northumberland Strait led to an assessment by Fisheries and Oceans Canada.”.

The Gulf of St. Lawrence is dyeing. We must do everything we can to help this ecosystem survive. We can not dump 90 million litres de oxygenated pollution daily into this body or water and expect it to survive. we can not continue on the same path.

There is not enough money in Canada to bring it back.
If WE stand by and let the Gulf of St. Lawrence die

Sincerely,

From:

Subject: MY EA Submission for Northern Pulps Replacement Effluent Treatment Facility Project
Date: March 10, 2019 12:00:57 AM
Attachments: EA Submission for Northern Pulps Replacement Effluent Treatment Facility Project.pdf

---

To whom this may concern,

Please see my attached comments regarding the Northern Pulp's Replacement Effluent Treatment Facility Project proposal.

Kind regards,

Environmental Assessment Branch
Nova Scotia Environment
P.O. Box 442
Halifax, NS, B3J 2P8

Dear Environmental Minister Margaret Miller,

I am writing in relation to Northern Pulp' s Replacement Effluent Treatment Facility Project proposal.

My personal connection to the Northumberland Strait comes from being born and raised in New Glasgow, NS. After high school, I left to pursue higher education and upon completing my degree in Leadership and International Development worked in the development field in Zambia and Guyana. I returned to Pictou County and it was upon my arrival that I learned of Northern Pulp's plan to pipe treated effluent into the Northumberland Strait—water that I grew up on. I have treasured memories of traveling to Prince Edward Island via the Northumberland Strait, and of time spent camping at Caribou-Munroe's Island Provincial Park. Returning as an adult this past summer I continued to take advantage of swimming in the Strait and walking its shoreline. Having grown up seeing the environmental impact of Northern Pulp on Boat Harbour and smelling and breathing the air emissions from its facility I felt it was important to review the company's Replacement Effluent Treatment Facility proposal as I'm concerned of its potential environmental impact.

Some of my concerns about the proposal and process include the following:

1. **The length and complexity of Northern Pulp's Replacement Effluent Treatment Facility Project proposal.** The 1600-page document and technical language used undoubtedly make it difficult for the average citizen to read and to be critical of the proposal. This will likely result in excluding much of the population that could be impacted by this project. Additionally, a 30-day period limits the number of people who are able to fully review and comment on the document.

2**. Potential risks to human health.** In section 9.0, page 489 of the proposal: Human Health Evaluation, Northern Pulp reports that "At this time, effluent chemistry characteristics (including the specific substances present in treated effluent and their anticipated concentrations) will not be known with certainty until the project is operational." It concerns me that this project could be approved without fulling understanding the potential health impact. If further investigation is not done on potential human health risks waiting until the project is operational may be too late.

3. **Northern Pulps claim of "No Significant Residual Environmental Effect".** In its Executive Summary, The company claims that out of 18 "Valued Environmental Components" none are considered to have a Significant Residual Environmental Effects. To me, this sounds massively optimistic and my question is what if the company is wrong? Based off my second concern

around health implications the company already admits that it doesn't actually know some of the potential impacts of this new facility.

Based off these concerns I sincerely hope you will consider rejecting the proposed Northern Pulp Replacement Effluent Treatment Facility Project. If you don't feel you can do this with the evidence before you, please call for a full Environmental Assessment report on this proposal.

Sincerely,

From: @gmail.com

Subject: Proposed Project Comments
Date: March 10, 2019 12:01:28 AM

Project: replacement_effluent_treatment_facility_project Comments: The issues with the Environmental Assessment start even before the Table of Contents. In the cover letter, Dillon Consulting mentions that they are submitting the document in accordance with requirements for a Class 1 project. Looking at the NS Environment website about Environmental Assessments https://novascotia.ca/nse/ea/faqs.asp, Pulp mill is listed explicitly as a Class 2 project. Additionally, this project also contains waste incineration plans for waste from the effluent treatment, which also qualifies for a Class 2 Assessment. Performing only a Class 1 assessment is a failure to follow the standards set out by Nova Scotia Environment. From here, the issues continue. Section 2.3 acknowledges that a full biological field assessments were not conducted to accelerate the process and to limit the period during which the mill would sit idle without a treatment facility. It then clarifies that the environmental effects have been defined based on existing available information from literature and other desktop information sources and that field data collection to complete the application will be conducted in Spring and Summer of 2019. By starting construction before the assessment has been completed, this assessment is assuming the outcome is a foregone conclusion - the project will have no impact on the environment. This is confirmed by the summary page. Unfortunately, due to the brief comment period allowed, I cannot perform an in-depth review of the entire 700 page assessment. I grew up in Pictou, and feel strongly that this project should not proceed. On a side note, I was living in a small town in Japan for the last 3 years. Several times I saw products available for purchase that were from Atlantic Canada - Lobster and Oysters. Never once have I seen a paper product proudly proclaiming provincial provenance - whether at home or abroad. There is no pride, no publicity, and no future for Nova Scotia in the paper industry. Northern Pulp Nova Scotia
Replacement Effluent Treatment Facility

N.S. ENVIRONMENT
ENVIRONMENT ASSESSMENT BRANCH
MAR 09 2019
RECEIVED

I am a Commercial Fisherman out of Caribou Wharf
I have fished out of Caribou for 32 years
I am presently fishing lobster, herring, and rock crab

I am asking the Nova Scotia Environment Minister to reject NPNS Replacement Effluent Treatment Facility, or in the very least, do a full environment assessment report on NPNS Replacement Effluent Treatment Facility for all the following reasons mentioned below.

Northern Pulp is asking the fisherman to believe in the science. I could not agree more.

Page 489 9.1
Human Health Evaluation

NPNS states, "At this time, effluent chemistry characteristic (including the specific substances present in treated effluent and their anticipated concentration) will not be known with certainty until the project is operational."

I believe that their Replacement Effluent Treatment Facility will harm the ecosystem of the Northumberland Strait.
-Which will be harm full to the fishing industry.
- Will affect the Tourist industry.
-This Environmental Assessment Registration Document is incomplete and shows misleading information.

How it will affect the fishery

NPNS is anticipating the effluent to meet compliance with federal PPER into Northumberland Strait. Page 120 E.

I bring your attention to Table 5.6-1 of page 120.
Total Suspended Solids, unit mg/L, value 48.

THIS IS THE MOST IMPORTMENT NUMBER OF THE ENTIRE DOCUMENT

And a quote from Stantec .
"Pg 345: From Stantec Preliminary RWS, May19 2017: "...Density of the effluent for modeling purposes was assumed to be 996.32 kg/m3. This density was estimated based on an assumed average effluent temperature of 37C and total dissolved solids (TDS) of 4 g/L (KSH, per comm 2017).

NPNS told us at the public meeting in Dec 2017 that this new system would release 5 to 20 % of the solid matter (TSS) into the Northumberland Strait, which would be estimated at 2000 pounds per day. As well, this toxic solid (TSS) would just go away.

The Fisherman Association has had conversation with leaders in this field and feel that 20 to 40 % is more of an obtainable number.

I did the math based on peak flow rate 85,000,000 L per day. I have 4080 kg per day or 8994.86 pounds per day. If my math is right, THAT'S A LOT OF TOXIC SOLIDS. See attachment.

Boat Harbour is approximately 360 acres. It takes between 30 and 45 days for the effluent to go through the number of stages before it reaches the Northumberland Strait. Where it enters the Strait, it is a very small waterway, with very little tide. (I would guess it is 200 feet across).

I believe that Boat Harbour is doing it job and that there is very little to no toxic solids (TSS) entering the Strait. NPNS new RETF is better than what is going into Boat Harbour, but it is NOT BETTER than what is coming out of Boat Harbour.

I believe the cost to clean up Boat Harbour is mainly because the toxic solids (TSS) that is left behind.

The Boat Harbour clean up is now estimated to be 217 million dollars to clean up the contaminated sediment at the bottom of the Boat Harbour lagoon.

NPNS explains on " Page 67 and 68 Table 4.2-4 " why is cannot go into Pictou Harbour and the Middle River.

NPNS is saying that Pictou Harbour will become another Boat Harbour because it has limited mixing.

NPNS says it will have the same affect on the Middle River, as well potentially effect the maintenance of the equipment at the Middle River Pumping Station and inside the mill. (Similar style impacts as described in regarding the use of a closed loop system above).

I am guessing that Pictou Harbour is 20 times bigger than Boat Harbour.

In these two statements, NPNS is stating that it will create another Boat Harbour effect on Pictou Harbour, and after it goes through a water treatment plant at the Middle River Pumping Station, it is still going to cause damage to their system. Accumulation of chlorides and potassium are especially corrosive for the mill's boilers and often to lead to scale build-up.

How is this a better plan?
How is this not going to have a negative affect in the Northumberland Strait?

Under a freedom of information act, our lawyer has found some very damaging information.
-NPNS technical manger said in an email in November 2017 that the effluent going into the Strait would be worse in the new outfall location than what is coming out of Boat Harbour now. Boat Harbour has a polishing affect now that the new one is missing.
-NPNS does not know what is in the effluent when it comes out of the new outfall location area.
- It was recommend to NPNS that a lobster larvae study be done.
Appendix 14 page 3
Lobster Larvae Study
NPNS/Dillon unable to respond to concern at this time; will investigate further.

Where the outfall is entering the Strait, is in a narrow channel. I believe that is 80 feet deep. You only have to go 100 yards north and you are in 40 feet of water, prime lobster bottom. You go 100 yards south; you are in 40 feet of water, where the Caribou Harbour channel begins.
Appendix E1 Page 18 Figure 3.1
They say the tide is going NW 54% of time and SE 31% of time. What is it doing the other 14% of time. Are we supposed to draw our own conclusion?

This is going to create a dead zone due to the following reasons.
-The increase in water temperature (25 c winter and 37c summer). Now high for the summer might be 20c, an adult human would find 37c to be uncomfortable. How is anything at a young critical stage going to survive?
-The amount of effluent and toxic solids (TSS)
-What is in the effluent, which is unknown?

I believe that the toxic matter (TSS) is going to have an affect on the existing fisheries.
My understanding is that effluent for pulp mills slow down the growth and reproduction system in a female lobster. But they say that they are still good to eat? Where is this toxic solid (TSS) going to settle? West as far as Toney River? East as far as Lismore? North as far as PEI?

Human Health Evaluation Page 540 shows a huge affected area.

I believe the out fall site (dead zone) will affect the future fisheries. Lobster larvae going through site will not survive.

How can we have sustainable fisheries?

Fisheries and Agriculture confirmed that 70 per cent of pulp and paper mills which meet (Pulp and Paper Effluent Regulation) cause harm to fish and fish habitat, and that Northern Pulp is one of the mills which are presently causing harm to fish habitat.

A study that was published in 2005 showed that outside Pictou Harbour, 30 % of mussels at a site 500 metres from Boat Harbour outfall had leukemia. At a site one kilometer from the same outfall, 23 % had leukemia.

In 2018, there was a shellfish closure where Boat Harbour enters the Strait. It ran 6 km east to Black Point. See attachment from Department of Fisheries.

How it will affect the Tourist Industry

I live across the road from the Munroes Island and Provincial Park entrance since 1985. Prior to that since 1969, I lived on Old Orchard Lane 200 meters from the waters edge, which is located between the Provincial Park and the Pictou Lodge. One individual that has a year round home and rents 30 yearly sites to seasonal trailers mostly owns this property. There is also four private owned cottages and one more year round house, all within 100 meters from the shoreline.

In the early 70s at that time the Pictou Lodge was closed, its front row of cabins was falling down its banks from erosion. This bank is roughly 75 feet high.

The fishing boats from Maritime Packers (which does not exist anymore) and the Caribou Ferry Wharf could take the Little Entrance, a channel that separated Munroe's Island from the Provincial Park beach, to the open water of the Strait. That has filled in 1979 due to a massive storm.

The province of Nova Scotia designated Munroes Island as a sanctuary around 2000, protecting birds, fish, and wild life. For more information, look under Caribou-Munroes Island Hiking Trails.

I have walked these beaches since 1969. In my 50 years, I have seen the affects that Mother Nature has on the area. The beach is one of best beaches in Pictou County, if not Nova Scotia. There is sand from Munroes Island to the point off Pictou Lodge. You can get strong winds from the north and the beach is covered in eelgrass and seaweed. This happens every fall.

The Provincial Park offers 95 campsites. It is often sold out in the summer months, and the beach is very well used by local people and out of town visitors. The Province of Nova Scotia has continually put money into the park doing upgrades. I see and hear the trucks in the offseason.

I think the Pictou Lodge speaks for its self as one of the nicest resorts in the Province of Nova Scotia.

When the park is closed in the offseason, every day I see cars parked at the entrance, a lot more on weekends, using the park and beach for walking, snow shoeing and skiing.

The outfall area is .9 km from Munroe's Island and roughly three km away from the Pictou Lodge. This effluent and toxic solids (TSS) is going to settle somewhere. With the tides and winds, how can the effluent and toxic solids not wind up in the eelgrass and seaweed, eventually landing on the beach from Munroe's Island to the Pictou Lodge? It will only be a matter of time before this area would not be safe for swimming and affecting the life of animals that exist on Munroe's Island.

Prior to Boat Harbour being build, the Pictou Harbour Light House beach was a fantastic place for swimming. It is very close to where Boat Harbour enters the Strait. Now it is not safe for swimming because of the effluent from Boat Harbour.

Environmental Assessment Registration Document is incomplete and shows misleading information

-NPNS is referring a lot of its information based on it original site off Pictou Harbour.
-NPNS was told by fisherman in their public meeting in Dec of 2017 that the site would not passed because it the water was too shallow and the ice would cause damage. It cost NPNS six million dollars to find out this same information. We were right.
-If survey work was done on NPNS second choice, what makes you think it would pass when their first choice failed?
-NPNS has no public meeting on their new site. NPNS says they don't have enough time.
- NPNS has not done any surveying, videotaping, test holes and core samples off this new site.
-I do not see in these documents (E1) 17 beta-estradiol (E2) estriol (E3) 17 alpha-ethinylestradiol receiving water studies.
-If the tide rises 54 % of the time at the outfall, where is Caribou Harbour getting it water? *When the tide raises it go into harbours.*
-NPNS has no information on the long-term affect of Caribou Harbour.
-NPNS has provided insignificant data through out these documents.
-NPNS has not done a lobster larvae study.
-There are new pulp mill regulations that come out in 2020. How does NPNS know they can meet them if we don't know what they are?
-NPNS environment impact may not be known until the future.

Section 8.12.2.5 pages 368 and 369
Showing maps of rock crab and Lobster.

I started fishing rock in 1990.
Personally, I am fishing rock in the channel where the diffuser is to be located. Going east as far as 5 miles east of Pictou Island, on the south side of Pictou Island fishing as close as you can get where the sand is, to three mile off Big Island. Meeting boats from Pictou Landing First Nation and Lismore, as well as other boat from Caribou.
See map attachment. I colored in red where I fish, and in green where I know other NS fisherman are fishing. I know boats from PEI fish out of Wood Island are fishing somewhere; I have to think that they are fishing where NS boats are not. I made a blue circle where I think they fish. Wherever there is soft bottom, someone is fishing rock crab.

I started fishing Lobsters in 1987.

When you buy a lobster license in this area of NS, you have to fish where the seller had fished in the past.

I am fishing lobster at the edge of the channel where the new out fall is proposed. Staying east of the ferry run, going north halfway to PEI where I meet up with the PEI boats. I know for a fact, in June, that boats from Caribou Harbour, Pictou Landing First Nation, Sinclair's Wharf and Lismore are fishing the soft bottom between NS shoreline to Pictou Island and heading east as far as they are allowed.

A boat from Lismore was charged this last spring for fishing over the line. IT'S TEN MILES OUT. Lobster fishing in our area is very good right now. Lobster catches are by far the highest in my 32 years of fishing. They are everywhere.

See map attachment. I colored in red where I am fishing. Colored in green is where I know other NS lobster boats are fishing. Also, circled in blue, is where I think PEI boats are fishing.

Page 495 and 496 9.2.1
Human Health Evaluation

" The specific pathways, and routes that were identified as being relevant for the project are as follows " It goes on to mention that PLFN has approximately 100 people in the commercial fishing industry.

Why is Caribou Harbour not listed? Caribou Harbour has around 70 commercial fishing boats listed as their homeport. Most boats have three people on them (210 people). There is also a few boats at Pictou Island Wharf and a few more at Sinclair's Wharf. During lobster season alone, there are three lobster buyers. One of them is North Nova Seafood's, which operates a fish plant in Caribou Harbour. In 2019, North Nova Seafood sent out around 500 T4 slips. Caribou Ferry Wharf is the central location of the commercial herring fishery. I believe in 2018, there were four herring buyers with boats from Pugwash and Cape Breton and everywhere in-between.

NPNS is so inaccurate in these maps and statements. I not sure if they are completely trying to mislead the public on how little fishing is in this area, or is NPNS using out dated information. In the meeting NPNS had with the fisherman in Dec 2017, they were not aware of any fishing done at the original site. The fisherman told them at that meeting their information is incorrect. NPNS was told at a stakeholder's meeting that their maps were incorrect. A phone call to the Department Of Fisheries in Pictou would verify how much fishing is done in this area.

If NPNS is so inaccurate and misleading on something so simple to find out the proper information, what does it say about finding out real science on the affect that the effluent and toxic solids (TSS) in going to have in the Northumberland Strait?

How can we trust NPNS science that is stated in this document, if they do not know what is in the effluent when it come out of the pipe?

At the Dec 2017 public meeting NPNS had with the fisherman, a fishermen's group representative from New Brunswick stated that Stantec did the work when the Confederation Bridge was built. The Stantec study showed building the bridge would not affect the lobster fisheries. The representative stated that they saw negative affect on the fisheries right away and took years for the fisheries to rebound.

Appendix E3 Page 4
Stantec, Sign-off sheet
-Reflects Stantec's professional judgment.
-Do not take into account any subsequent changes.
-Did not verify information supplied by others.
-Not responsible for cost or damages of any kind.

Appendix C Page 19
KSH Disclaimer
-Should not be viewed as definitive.
- Does not guarantee such accuracy of such estimates.
-Bear no responsibility.

NPNS used this words a lot –Best industry practice
-Minimize potential impact
-Anticipate
-Not recommended
- Not significant adverse

I have one phase for the Minister, PERCAUTIONARY PRINCIPAL.

It comes down to the Province of Nova Scotia taking all the liability responsibility when this Effluent Replacement Treatment Facility fails.

Page 441 8.14.4.2
Commercial Fisheries and Aquaculture Compensation

First paragraph states, "The potential of the project to impact commercial fisheries and aquaculture could occur from effects on marine population, damage to vessels or gear, or interruption to loss to access to ground."
During the NPNS public meeting with the fisherman in Dec 2017, it was directly asked if there was going to be a bumper zone put around the out fall, and how big of an area would be closed for shellfish? We are still waiting for the answer.

Since I fish where this outfall is located, my income is going to be directly affected, and I will be one of the first fishermen in line to sue.

I am asking the Environment Minister of Nova Scotia to reject NPNS Replacement Treatment Effluent Facility, or the very least, order a full environment assessment report on NPNS Replacement Treatment Effluent Replacement Facility.

March, 04, 2019

$48 \frac{mg}{L}$ $85{,}000 m^3$ per day

$1 m^3 = 1000 L$

$85{,}000 \cancel{m^3} \times \frac{1000 L}{1 \cancel{m^3}} = 85{,}000{,}000 L$ per day

$48 \frac{mg}{\cancel{L}} \times 85{,}000{,}000 \frac{\cancel{L}}{day} = 4{,}080{,}000{,}000 \frac{mg}{day}$

$1 mg = 1 \times 10^{-6} kg$

$4{,}080{,}000{,}000 \frac{\cancel{mg}}{day} \times \frac{1 \times 10^{-6} kg}{1 \cancel{mg}} = 4080 kg/day$

$1 kg = 2.20462$ pounds

$4080 \frac{\cancel{kg}}{day} \times 2.20462 \frac{pounds}{\cancel{kg}} = 8994.86$ pounds/day

$4080 \frac{kg}{day}$ or $8994.86 \frac{pounds}{day}$

Home

Check the map and Prohibition Orders before harvesting!

For fishing seasons, size and quota limits refer to the Regulations and Variation Orders under the Fisheries Act. Contact your local DFO office for details.

Anyone harvesting bivalve shellfish, i.e. shellfish with two shells, including all clam species, oysters, cockles, mussels and scallops, is responsible for ensuring that an area is designated as safe for harvesting. Eating contaminated shellfish can cause serious illness or be fatal.

Shellfish should not be harvested in unmonitored areas or within 125 metres (410 feet) of a wharf, a marina, an aquaculture operation or a floating house. Unless clearly stated otherwise, all closures extend to the coastline.

Legend

- **Green** areas are **approved** for harvesting of all species of bivalve molluscs

1)

March 6, 2019

Dear Ms. Miller,

My name is , and I live in Pictou, Nova Scotia with my husband. We have raised our daughter in Pictou and she is now a university student. I am a graduate of The University of Toronto. I am not a scientist, but have many years of lived experience with issues of environment, nature and health. As a young girl, I kept tropical fish, and I learned much about the fragility of marine life through my experiences.

I am writing to you with my concerns regarding The Replacement Effluent Treatment Facility Project, submitted by Northern Pulp.

I have many grave concerns about the possibility that NP would be allowed to go ahead with this project.

My first concern, which is a general one, is that the size of this document alone would warrant much more scrutiny than a Class 1 assessment would give it. The contents of this document are extremely complex and would affect the environment around Pictou , the environment in Caribou, and the waters of the Northumberland Strait, which assuredly impacts all of Atlantic Canada's provinces. It is too long to read through and say that it is a simple project in any way.

My second concern: Under Key Federal Regulations on page 20, (Section 3.2) NP claims that no Federal EA triggers have been determined. I dispute the classification that this treatment facility is an extension of the old one. It is completely new in it's many plans. The building of a pipe, running it to the Northumberland Strait, is not at all an extension of Boat Harbour. (However, I suppose it is the same in the fact that they plan to throw their trash into another body of water, rather than build a container to hold it.) I look at Boat Harbour and it's destruction and know that destruction will only increase if a direct pipe goes into the Northumberland Strait. If it is indeed the "same" plan, then an EA Assessment would seem vital to maintain the health of the ocean they intend to use to receive their garbage/effluent.

My Third concern: On page 50, (section 5.3.1.1) NP claims that all construction will take place on their right of way boundaries. However,the proposed pipe would run alongside the Watershed for the town of Pictou. If only the effluent running through the pipe understands those boundaries too! Given the record of NP's pipe failures and spillage, and given the fact that monitoring is minimally carried out at best, disaster would be imminent for the drinking water for the town of Pictou. There is nothing more necessary

for human life than clean water. Nothing. Pipes break. And pipes buried under the ground don't reveal the spillage until the damage has already occurred.

in addition to this, NP's massive use of fresh water is an obscene waste. They have been draining the water tables in Pictou county for decades, rather than build a closed loop system. It is 2019. We have knowledge that our lifegiving resources are being depleted.

My Fourth Concern: On page 45, (Section 5.2.2.8 paragraph 4) they state that the sludge from the effluent will be burned in their existing power boiler. My God! The sludge will go into the air and everyone will breath it! And the power boiler is a malfunctioning piece of aged machinery. They state that this sludge "partially displaces the use of fossil fuel." They won't use a closed loop to save on water consumption, but make a feeble attempt in this statement to make it seem like they are conservation minded by reducing their use of fossil fuel. And all the while, depending on an aged and malfunctioning power boiler that never meets the low standards that government has outlined for it! This sludge will contain many toxins. I site the visual containment at Boat Harbour. Boat Harbour is now so polluted that careful cleanup costing millions (or billions) is necessary. There was a reason for containment, and putting that garbage into the air distributes it very quickly into people's bodies. Wow.

My Fifth Concern: In this NP document there are many pages of the description of the work to be done to lay the pipe. It is vast and complicated, and also speaks of this project not being an extension of the present containment at Boat Harbour. (And thus ineligible for a quick assessment.) Some of these descriptions sound like clearcutting around our Pictou town area. On page 52,(Section 5.3.1.4) they describe "grubbing" which is removing stumps, vegetation and top soil. They write of conserving topsoil. Thousands of acres of clearcutting all across the province and they have never once "conserved topsoil." On page 51 (Section 5.3.1.3 Paragraph 4) they refer to paying attention to bird migrations and nesting. Having seen and read of their clearcutting in Nova Scotia, I know they don't pay any attention to these issues. I can only conclude from these statements that they are lying.

My Sixth concern: on Page 79 (Section 5.3.2.4) they state that this pipeline will last for 50 to 100 years. Imagine the state of the Northumberland Strait after all that time. I've seen Boat Harbour. There is not enough"dilution" in any body of fresh natural water to dilute the massive amount of heated foreign substance that will accumulate.
Add to that the state of our forests. They are disappearing at an alarming rate. In 50 to 100 years what trees will we have? This is all unacceptable, unsustainable. Do you have children and grandchildren? Don't you care that after we are gone we will leave our children and grandchildren a blighted poisoned world? Because allowing this is happen will create a diminished world. An ugly unliveable world.

Then they go onto say on the same page the amount of heated effluent to be discharged into the Strait on a daily basis. The numbers are astounding, mind boggling. 62,000 m3 to 85000 m3 per day! 1m3 equals 1000 litres! There is an insanity to this. Million and millions of litres created with our fresh water from our water

3)

tables and thrown,heated, into the fragile and temperature sensitive saline environment of our Strait, from which we get our food. So, food and water destroyed wantonly in this process. Unimaginable, but if allowed, horrifying. Destruction of the environment on a massive scale.

Top of page 84: (Section 5.6.1 E) "The effluent is expected to meet requirements…. " But even if you put heated fresh water with NO effluent in it into the Strait in those quantities, we would have a vast warming of that ocean. We now have enough evidence now that the temperature of oceans are rising, and changing life/climate on this planet for the worse. If this effluent actually meets any requirements, then the requirements must be changed.

And I finish my letter to you with this: On page 88, (Section 5.7.1) NP states they are "committed to developing this project in an environmentally sustainable manner.." I have never seen them operate in an environmentally sustainable manner. I live in the town of Pictou and have experienced daily what you, the government, have let them get away with. If they were intending to operate environmentally they would build a new plant, with new stacks and power boiler, a closed loop system and container for their effluent. Boat Harbour would have ceased to be an issue and they would have cleaned it up themselves instead of letting the taxpayers of Nova Scotia pay for that.

This document is set up to read well, but it contains horrors. I ask you, I implore you to send this proposal off to the CEAA. Or stop this nonsense right here and now and shutter this wretched company. Jobs to replace the mill can be found, with determination and imagination. But life, water, food, and natural resources can never be reclaimed if this plan is allowed to go forward. Never.

Sincerely,

@gmail.com

Replacement Effluent Treatment Facility Project
Environmental Assessment Branch
Nova Scotia Environment
P.O. Box 442
Halifax, NS, B3J 2P8

To Whom It May Concern:

We are writing on behalf of the Nova Scotia Salmon Association (NSSA) and the Atlantic Salmon Federation (ASF) concerning the environmental assessment (EA) of the proposed replacement effluent treatment facility being advanced by Northern Pulp Nova Scotia Corporation. The NSSA and ASF have a good working relationship with the proponent, as Northern Pulp Nova Scotia Corporation has been supportive of our salmon recovery work through numerous in-kind contributions, and we actively consulted with the company in the lead up to their EA filing. However, upon reviewing the environmental assessment registration document, we have concerns and reservations about the proposed project and its potential effects on wild Atlantic salmon and the ecosystem that supports them in this important region.

Nova Scotia's Northumberland Strait coastline is home to 15 salmon bearing rivers between Amherst and Antigonish. Part of the Southern Gulf of St. Lawrence population complex, Atlantic salmon in this area have been assessed as a *species of special concern* by the Committee on the Status of Endangered Wildlife in Canada (COSEWIC). This designation was assigned due to long-term trends of population decline and a multitude of current threats. COSEWIC members also considered the fact that nearby Atlantic salmon populations have been listed as endangered under Canada's *Species at Risk Act*, or have been recommended for an endangered listing.

The designation of Atlantic salmon in this area as a species of special concern is important to the environmental assessment process because salmon are an ecological keystone species that provide insight and perspective to the status of other foundational fish like gaspereau and smelt. The health of salmon populations is a general indicator of overall ecosystem health. We therefore feel it is especially important that the principles and values espoused by the N.S. Environment Act be rigorously applied to this and other developments in the area.

During consultations with Northern Pulp prior to the EA filing, we identified several areas with respect to wild Atlantic Salmon where their research was data-deficient. We offered to assist in gathering the information required. The most concerning deficiency was a lack of information with respect to how the proposed outfall impact zone will overlap with salmon migration routes and salmonid congregation points spatially and temporally at critical life stages. This data gap was not addressed, but is noted by the proponent in their EA filing (Section 8.6.2.4 page 217). Although the effluent coming out of the outlets will meet specifications of federal *Pulp and Paper Effluent Regulations*, those regulations mandate that the effluent be further diluted within a prescribed distance from the outlet. These dilutions are necessary to ensure the receiving water meets acceptable parameters for biological oxygen demand, chemical oxygen demand, temperature, salinity, etc. in order to ensure aquatic life will not be harmed and ecosystems not disrupted.

Given the need for dilution, even compliant designs will create an impact zone where negative effects will occur. To fully understand the risks posed by this impact zone it is crucial to understand how the impact zone will overlap spatially and temporally with sensitive species, such as Atlantic Salmon in this area. Without this baseline data it is not possible to predict impacts or monitor and validate actual impacts once the facility is in operation. This severe limitation has been raised with the Provincial Fisheries Minister's staff and the proponent.

There was also a deficiency with respect to the impact zone modelling done by the proponent. Although we recognize modelling necessitates some educated guesswork, the assumptions used in the EA registration document, such as ambient temperatures and time of year, were not in line with when wild Atlantic salmon would likely be present in the impact zone, i.e. during the spring and fall congregation and migration periods. It is clear from the filing documents that there is some misunderstanding by the proponent of the biology and behavior of the species involved. For example, they cite papers noting that Atlantic salmon swim in the upper portion of the water column and suggest there will be a minimal impact because the outlet pipes are on the seafloor. This assumption is incorrect because while migrating Atlantic salmon are indeed pelagic (associated with the water column) as opposed to benthic (associated with the sea floor) the shallowness of the depths involved with the outfall and the impact zone will be well within the zone that would be occupied by salmon, and many other important fish species, migrating and congregating in that geographic area.

We were disappointed upon seeing Northern Pulp's EA filing that deficiencies identified ahead of time were not addressed and there does not appear to be a plan to do so. This is a major oversight that needs to be corrected before any consideration of releasing the project from the assessment process. Given the potential for negative impacts, the threats currently faced by salmon, and what they represent within the ecosystem, we cannot afford to have this or any other operation cause unintended negative consequences. It is therefore essential to the ongoing environmental assessment process that proper baseline data is collected over the appropriate spatial and temporal scale. It is only with proper baseline data that the extent of potential impacts can be assessed, that effective monitoring can occur, and that mitigation and adaptive management plans can be developed and implemented as necessary.

From our research and consultations, we have also identified several other areas of concern that are not adequately addressed in the proponent's EA documents. For example, compared to Boat Harbour, the new treatment facility will reduce the capacity to hold <u>untreated</u> effluent in the event of an emergency from 30 days down to a proponent-estimated 8-12 hours. Although it is known to occur, there is no publicly available information on how often an untreated effluent is required to be held each year and the duration of those periods. Given the size, age, and complexity of the mill, a capacity of only 8-12 hours seems insufficient for operators to identify and rectify problems, or to idle the plant while the problem is being fixed. The filing is also vague on how the proponent is planning to provide real-time monitoring of the effluent and how the company will deal with other emergency issues associated with effluent treatment and containment. Given the current regulations surrounding monitoring of effluent (monthly acute lethality testing) coupled with this uncertainty in monitoring and holding capacity this would mean that untreated effluent could potentially be discharged for a significant period of time before it would be detected and stopped by the proponent or detected by legally mandated monitoring. This is a serious concern. Therefore the holding capacity issue and emergency action plans involving effluent treatment and mill idling need to be addressed within the filing documents in order to properly assess the potential

impacts of this project and develop appropriate monitoring and reporting conditions for the facility's operation.

Another area of concern is with the transition in effluent systems from the current Aerated Stabilization Basin treatment (ASB) system to the proposed biological Activated Sludge Treatment (AST) system. While these newer systems have shown they can provide higher BOD reduction efficiency, they are more susceptible to settling issues and disruption to the biological community that is central to this effluent treatment process. So called biological upset can occur regularly if not carefully managed by experienced operators. Therefore, this new system will require more highly trained operators and more testing to maintain effluent below legally required levels. The EA filing does not address these challenges associated with the changeover in process. The filing documents do not identify what testing will occur to ensure that the new system will be working efficiently and within desired parameters prior to the switch over from the ASB system nor the mechanisms that will be put in place to ensure proficiency of their operators and the operational procedures for the new facility. There is also a lack of information concerning procedures for detecting and mitigating known issues such as biological shock, bulking, or for other failures within the treatment facility or within the mill. Failures in any one of these areas could lead to untreated effluent being pumped into Northumberland Strait, relying only on voluntary transparency by the proponent and the federally mandated monthly testing to detect the issue. This is a significant failure in the EA. More information is required before an informed decision can be reached on this project.

The outfall diffuser location is also an area of concern. The proposed location of the outfall diffusers is just beyond the inlet to Caribou Harbour. This area is known to have issues with sedimentation, infilling, and ice scour. It is not clear from the EA filing if this has been considered and how infilling may affect the performance of the diffusers. It is conceivable that it could result in blockages that would disrupt the diffusion patterns that are needed to ensure proper mixing to get the effluent within the legally required tolerance levels at the prescribed distances from the outflow pipe. As there is no information on the spatial and temporal distribution of fish migration routes or congregation points it is difficult to predict how changes to diffusion patterns could affect salmonids and other species. Additionally, the concealed nature of the diffusers means that issues with the effluent or with the diffusion pattern may not be detected in a timely manner.

On behalf of NSSA, ASF, our affiliates, associated members, and volunteers we urge the NS Environmental Assessment Branch to require that this project be subject to the most rigorous standards to ensure that this highly sensitive and ecologically important area is protected. The provincial Level 1 EA submitted by the proponent is insufficient for achieving this standard. Due to the potential to release deleterious substances and threaten species at risk and the potential to have multijurisdictional impacts, this review should be conducted via the federal environmental assessment process. Regardless of that decision, we will continue working to ensure that the best interests of the ecosystem and salmonids are represented and protected.

Sincerely,

President
Nova Scotia Salmon Association

Director of NS and PEI Regional Programs
Atlantic Salmon Federation

The Northern Pulp and Paper Mill has been poisoning the environment surrounding Abercrombie Point from the day it started production.
The pollutants released into the atmosphere have been dispersed over Eastern Canada and beyond.
It has interacted with similar- blowing across North America and within the atmospheric chemistry creating products that are detrimental to the ecosystem of all air breathing lifeforms and subsequently ending up in the water systems for the future to absorb.
A large part of what is produced in this mill is now sitting in landfills all over the continent.
The destruction,disruption of the ecosystems and diversity of natural wildlife in the woodlands that are being mowed down to feed this operation and the loss of its maximum global warming carbon dioxide absorbing /recycling capability is short sighted.
The fossil fuels burnt in the power generation plant to provide the electricity to run this operation create more pollution and carbon dioxide emisions as well as increased electromagnetic field emissions ...as do the logging trucks and logging operations and not to downplay the dangers imposed by their presence on the rural highways.
From the beginning residents living around this plant for miles have suffered from the stink and health effects of breathing this mix of slow poisons.
Those near the Boat Harbour dump have been unknowingly infected much more.
A common rule of law states that a person has reasonable right of enjoyment of their property.
This plant is in violation of that right.
The concept of pumping this scientifically treated effluent into the Northumberland Straight-out of sight and out of mind of the locals is doomsday for the marine ecosystems there and beyond.
The ocean is still relatively natural and useable as a food source in comparison to our land based sources which are increasingly being chemically and genetically enhanced and disturbingly modified by human ingenuity.
The ocean has provided long term and until recently -sustainable- income to many.
How does the pollution created by the same number of jobs in the fishing industry compare to that of this plant?
...and which occupation has more value to the community other than money?
The concept of tax dollars being used/donated to create some jobs for a few decades??? with no concerns for the long term effects on the environment and its ability to feed all of life's myriad of interdependent organisms is in violation of a governments legal-duty of care- and negligent.
The question arises -if it is now pure enough for the Straight why are they going to the trubble to pump this thru a pipe out there?Why not just dump it into Pictou harbour.Why not put it in swimming pools /lagoons on the site and properties of those making money from this and require them to swim,bath,wash their cloths and water their gardens, for a period of time to show all how pure they believe this to be.Why couldn't it be shipped in tankers to the yards,neighbourhood of its owners?
...and what else might find its way out there under the cover of darkness?
...and how does this chemically mix with all the other chemicals,drugs,plastics,etc.now working their way downhill towards the ocean from our septic systems and landfills ?
It's reprecussions will become evident in time and beyond repair.

A small percentage of the community have benefitted financially from the plant and the health care and drug store businesses.are assured to prosper into the future.
The wealth of few have affected the health of all.
The original minds that put this there have all grabbed their spoils and slithered away with no accountability for their short sighted efforts.
This plant is old technology wise and has been paying for itself and may still be viable for a few years more?? but it's time is near.
It has left its legacy for the future to deal with.
The minds and backgrounds of previous governments have donated tax dollars to this business in support of the wealth and witl spend more in health care for the elderly because of the health effects from its pollution.
The expression -know when to fold 'em -has merit in this case
The loss of the jobs for those responsible for this can be viewed as the best thing that has

happened to the community since this plant began.They can be viewed as accomplices to a crime.

It would be but a minor blink to the local economy and would open up development opportunities for the town of Pictou that are now being repressed because of its annoying unpredictable stink.

Employment opportunities come and go thruout any community thruout any year.Some empoyees have job skills that will be of value.

Tax dollars can be invested in others to re-educate,retrain,relocate and temporarilly support their living needs.

The community can be called upon to help them in their time of duress.

The community as a whole is better off in the long term to not have all its eggs in one basket owned and controlled by some come from aways!

thank you

Dear Sir/Madam

Re: Northern Pulp Proposed Replacement Effluent Treatment Facility Project

To introduce ourselves, we are retired, in our early 70's & reside on Caribou Island, directly facing Caribou Harbour. We love our view of the harbour, the water, beaches & air quality except when there is a southwest wind. That is when we get the putrid toxic plume from the pulp mill which was supposed to have been remediated years ago at great expense to the taxpayers of this Province. Nothing was ever done & probably never will be. Our lives & health have been directly impacted due to the mill's total disrespect & disregard for people in this community.

In all due respect, we vehemently reject the Project because of the likelihood that it will cause adverse effects & additional devastating environmental effects that cannot be mitigated.

At best, the proposed Project is a case study, based on just bits & pieces of unprovable data with the entire process lacking in credibility. There were never any public consultation meetings by Northern Pulp on the proposed project; in fact the only consultation made was on the wrong project; i.e.: Pictou Harbour.

The voluminous registration document is rife with unsubstantiated & very confusing data. As one example we refer you to the Table of Contents, Section 7.0, Sub-Sections 7.4 - Factors to be Considered & 7.41 - Scope of Factors to be Considered. By the consulting engineers own admission, their "Scope Sign-off Sheet" is at best based on unverified information supplied by others, hearsay, etc. for which they assume no responsibility. A Scope of Work should contain any milestones, reports, deliverables, time lines & note the biggest risks to the successful (Not Defensible) completion of this type project, just to name a few. In our view this alone defeats the Project!

Add to all this is the fact that Northern Pulp does not know just exactly what the effluent is comprised of. Yet they want to pump millions upon millions of this toxic sludge into our waters with no concerns for our health, the environment, tourism, wildlife, fish habitant and absolutely no appreciation for nature, just to name a few. Just exactly what would be the long term effects on Caribou Harbour? There is no long term data providing any insight and what data is provided is totally insufficient. Why should that be surprising considering the study is based on the Pictou Harbour route.

There are no provisions to protect our ecosystems & not even enough data to meet current regulations.

Very questionable & misleading information is contained in various parts of Appendix E3 - Preliminary Receiving Water Study. For example, please note Sec. 2.0 - Far Field Modelling, Sub. Section 2.1.2.5 - Currents. This information is old data and again based on Pictou Harbour, not Caribou Harbour. Also, please carefully note Sub. Section 4.2.2 - Ice Conditions, which states among other factors and it is emphasized that ice conditions in the Northumberland Strait are highly variable and the ice cover varies considerably from year to year.

The Caribou Harbour ecosystem is constantly evolving and will not survive the adverse effects should Northern Pulp's effluent be allowed to be dumped into the Strait! We do not feel any portion of the process has been fair to the community at large. We feel that Northern Pulp have failed the test and the undertaking should be rejected. At the very least, the Project should undergo a Class 2 EA.

Respectfully Submitted

Replacement Effluent Treatment Facility Project.

Attachments

- Term Employees Employed at Northern Pulp 2018
- No Plan B Possible Forestry Sector - Northern Pulp/Paper Excellence Canada

The following comments are submitted on behalf of the Membership of UA Local 244 Antigonish Plumbers, Pipefitters, Welders, Instrument Technicians and Apprentices.

Our comments include concerns of the entire Construction Industry Management and Labour.

My name is , Business Manager of UA Local 244.

I am a Red Seal Steamfitter - Pipefitter by Trade.

My first Industrial Job was the Pulp Mill currently owned by Northern Pulp.

Most of our comments will refer to negative socio economic issues.

Northern Pulp is a Company that puts 2.1 Billion Dollars Per Year into the Provincial Economy.

We have an experienced Construction Industry to build the new Effluent Plant.

We will leave technology and scientific comments to the Professionals in those areas.

The Construction Industry has not been included in any of the negatively affected Groups, that would lose jobs.

The attached "Term Employees" indicates Trades People who worked directly for Northern Pulp during 2018 when extra help was needed inside the Mill.

That totals 180 Employees and $1,409,715.52 for the year. This has continued over the 52 years that Mill has been there and in most years the numbers were much greater . This number does not include other Trades People and Employees of Contractors who were employed in the Mill. The new Effluent Plant would be an 18 Month Project.

A Brief History

Many of the Senior Nova Scotia Tradespeople worked at the Mill in 1965-66-67 during Construction.

Fishing was so bad up in River John, Tatamagouche, Wallace and Pugwash Areas that many fisherman from the Area joined the Construction Unions and only a very few left the Mill during Construction to go fishing .

The hourly rate for Pipefitters at the time as $3.80 per hour and that was more than a Lobster Fisherman could make at the time.

To this day a large number of Fisherman are Tradespeople in the Construction Industry when Fishing Seasons are closed.

For about the first 30 years or more the effluent was black going into Boat Harbour and black going out into Pictou Harbour from where it went out into the Strait. Not that it was a good thing but the Fishing Industry has been thriving during the past 52 years without negative effects from the Mill.

Recently a Fisherman Friend told me that the prevailing water flow in the Strait goes up and around Prince Edward Island. That would mean the effluent from the Mill would also be going the same direction and there has been record lobster catches up around the Prince Edward Island Causeway in recent years.

Plan B - There is none!

Any long term Nova Scotia Taxpayer would remember how successive Governments of all the Party's spent massive amounts of Taxpayer money on "Make Work Projects" that produced little or nothing. Probably in the billions.

Northern Pulp wants to Clean Up the mess they inherited when they bought the Mill in 2011. Whether it was previous Owners or previous Governments that wanted to run Boat Harbour. None of it should of happened the way it did.

That is all in the past and Northern Pulp is not responsible for it.

Everyone needs to face up to the fact that Rural Nova Scotia has not been doing well for many years. Northern Pulp is the Key Player in a highly integrated supply and demand system that the whole economic system benefits from.

Everyone loses when a major Industry shuts down.

Even those who would think of it as a win would soon realize:

- their taxes are going up,
- they can't sell their property for half of what it is worth,

- Hospitals will become First Aid Stations,
- Schools would close because the last of your Family Members will have to move away to find work.
- Poverty, Employment Insurance and Welfare will all dramatically increase.

I repeat THERE IS NO PLAN B and there never has been one.

There is a Plan A however. Leave good enough alone!

Grant Northern Pulp an extension on the use of Boat Harbour until the new Effluent Plant is up and running. The Nova Scotia Government should pay the Natives in Pictou Landing a negotiated amount for their inconvenience.

There is a Win Win Solution for every problem if enough effort is put forward.

I agree that the Residents of Pictou Landing and Surrounding Area have been negatively affected by the whole Boat Harbour fiasco for Fifty Two years. I also agree that it should be closed but to me it looks like successive Governments have signed up to be responsible for everything. The current Government has taken an aggressive approach with Northern Pulp by cancelling a legal agreement with Northern Pulp to operate Boat Harbour until 2030.

The cancelling of that Agreement in 2014 reduced the length of the Lease by 10 years and 11 months.

In 2015 the Government tried to force and unrealistic Industrial Approval on Northern Pulp. Northern Pulp appealed and it went to Supreme Court. On the first day of Court the Government backed off on the issues under appeal, however this would of cost the Company many hundreds of thousands of dollars in legal fees and preparations.

The Boat Harbour Act also became Law in 2015 along with the five year deadline.

Most if not all of this was done with no consultation with the Mill. Without getting into all the details Northern Pulp has had their hands tied by several Branches of Government before the arbitrary deadline was put in place and it still continues with the Government pointing the finger at Northern Pulp that you should be ready.

My take on the cancellation of the Boat Harbour Lease to Northern Pulp Ten Years and Eleven Months early could leave the Nova Scotia Government fully responsible for all expenses and lost profit incurred by Northern Pulp.

Not to mentions the complete demolition and cleanup if Northern Pulp is forced out of Business.

At one of the earlier Open House meetings Chief Andrea Paul spoke about the closure of Boat Harbour. Some of the Environmentalists in the room started pushing for the closure of Northern Pulp. Chief Andrea Paul got up and said we never asked for the Mill to be Shut Down we just want Boat Harbour cleaned up.

I have no idea how this has evolved to a point where two people, Premier Stephen McNeil and Chief Andrea Paul have the authority to Shut Down a huge portion of a very fragile economy.

The best solution for everyone would go something like this..

The only way to avoid Northern Pulp from being shut down is to grant an extension of the operation of Boat Harbour until the new effluent plant at Northern Pulp is up and running.

The Government of Nova Scotia signed off on a deal to close Boat Harbour and dictated a date of closure without consulting the Industries effected.

The Government has been in negotiations in regard to compensation for the closure of Boat Harbour so they are on the hook.

The Agreement on the closure date for Boat Harbour was made between the Government and Pictou Landing Chief Andrea Paul.

I know Pictou Landing is not a rich community and they do deserve to be compensated if the Government does not live up to the closing date of January 31/2020.

THE NOVA SCOTIA GOVERNMENT IS LIABLE

The question is, do they want to be liable for destroying several Industries with the Shut Down of Northern Pulp or pay Pictou Landing Residents what it is worth to extend the Boat Harbour closure date until the new effluent plant is complete.

Either way the Natives would see the closure of Boat Harbour.

The new effluent plant proposed by Northern Pulp will have a positive effect on the Environment as well as Employment and the socio economic situation in the Province.

In a CBC Interview with the Premier in Sydney over Christmas there was some suggestion that if Northern Pulp closed we would still have one Mill in the Province. That other Mill has already cut Producers to the bare bone as it is, just imagine if there was no competition. I expect the Forest Industry will speak for themselves on that issue.

It is time that common sense comes to the table. Northern Pulp wants to clean the Mill up to world class standards.

Sincerely,

Business Manager

NORTHERN PULP
NOVA SCOTIA CORPORATION
A PAPER EXCELLENCE COMPANY

March 6, 2019

For Immediate Release

No Plan B Possible for Forestry Sector

(Abercrombie, NS) Last week, both Premier Stephen McNeil and Progressive Conservative leader Tim Houston had an opportunity to debate the future of the forestry sector. Lacking in the conversation was discussion regarding providing Northern Pulp with a short extension to complete its new wastewater treatment facility.

"It needs to be said: without Northern Pulp there can be no plan B that does not include massive job losses," states Jean Francois Guillot, Vice President Operations East with Paper Excellence Canada, owner of Northern Pulp. "The forestry sector's future was discussed in the legislature last week, but no one discussed a short extension for our wastewater treatment facility."

"Without a short extension, we will be forced by the government to cease operating and that will cost jobs throughout rural Nova Scotia."

Northern Pulp's new wastewater treatment facility will ensure no untreated wastewater ever leaves the site and will then continue our practice of releasing treated wastewater into the Northumberland Strait. "Once this new project is completed, we will be one of the most environmentally responsible mills in Canada," said Guillot. "We too want to see Boat Harbour cleaned up, we want to finish our new treatment facility; we just need a little bit more time to get that done."

"Our partnerships with sawmills, forestry contractors and private woodlot owners are critical to its success and the rural economy," said Guillot. "Our new wastewater facility will reduce our environmental impact while ensuring we can continue to help the Nova Scotian economy."

"Any plan for the future of the forestry sector that does not include Northern Pulp will be a plan for the managed decline of the sector in Nova Scotia."

There must be further assessment as so much is at stake for NS and PEI and NB. We do not know the ingredients. They will start burning contaminated sludge without a thorough study of emission concerns, the environment, the fisheries, sea life and tourism. All are at risk the strait can freeze so how will the warmth flow impact lobster spawning grounds. Much further studies need to be done. Thank you
